Today, technologies like the Family Radio Service, high-speed telephone & cable modems, the Internet, and inexpensive cellular telephones, have overshadowed the privileges of the Amateur Radio Service, and made the requirements for young beginners to obtain a Technician Class license out of date. Additionally, the Technician Class license has now evolved into a beginning and ending point for most modern day Amateurs, who are mostly interested in VHF/UHF communications, rather than HF communications. Incentive licensing has virtually been eliminated.

The need for a Service dedicated to the goal of teaching young radio users proper radio operation techniques and etiquette can clearly be seen in the disarray present on the 11 meter Citizen's Band Service frequencies. The fact is, the Citizen's Band has become the defacto introductory service for young people just beginning to learn to experiment with radio; yet the Citizen's Band is a very poor environment for young people to be learning in.

Therefore, it is recommended that a new "Colt Class" license be added to the Amateur Radio Service expressly to encourage young individuals to enter the Amateur Radio Service to improve their understanding of RF communications theory, provide a healthy learning environment, and encourage radio experimentation.

On the 70cm UHF band, Colt licensees would be restricted to voice communications on 5 simplex-only 20khz-spaced channels on 446.00, 446.02, 446.04, 446.06, and 446.08 Mhz; and digital communications up to 19,200bps on 1 simplex-only 60khz bandwidth channel on 446.14Mhz.

On the 1.25m VHF band, Colt licensees would be restricted to voice communications on 5 simplex-only 20khz-spaced channels on 223.42, 223.44, 223.46, 223.48, and 223.50 Mhz; and digital communications up to 19,200bps on 1 simplex-only 60khz bandwidth channel on 223.56Mhz.

To encourage experimentation/understanding of antenna and VHF/UHF RF propagation theory, Colt licensees would also be allowed to setup and/or operate through a VHF/UHF crossband, simplex user input/output, repeater station on two 20khz-bandwidth channels on 223.52Mhz and 446.10Mhz. This would allow them to setup an inexpensive repeater system by interconnecting the voice/mic connections via a resistive circuit on two simplex radios; and

would not require expensive, and difficult to understand, cavity and duplexer filtering at the repeater station site. User radio costs would be low, as they would only need a single simplex radio. As a result of the characteristics of this type of repeater, the repeater builders and users would learn to coordinate frequencies, and user groupings based on environmental conditions, so as to acheive optimal results.

Colt license users would also be subject to the following restrictions:

(1) Individuals applying for a Colt Class license must be under 19 years of age at the time of license application or renewal. The license is valid for 5 years.

(2) Fixed control station antennas will be no more than 6.1 meters (20 feet) above the ground or above the building or tree on which it is mounted.

(3) Transmissions limited to 5 watts ERP, or less.

The new license class would have the following goals:

1) Encourage more young people to enter the Amateur Radio Service, by providing an entry-level ARS license class that includes privileges allowing reliable short-range voice and data communications.

2) Not significantly impact existing users of the affected Amateur Radio Service frequency bands.

3) Encourage basic knowledge of radio, electronics, operating principles and etiquette among a wider segment of the general
population.

4) Take advantage of the success of the Family Radio Service, and provide a path for those young users interested in further radio experimentation.

The Colt license exam would consist of 25 fairly simple questions. Emphasis would be put on understanding the existing operational, safety, etiquette and emergency questions from theTechnician Class question pool that relate specifically to Colt Class license privileges. All questions containing calculations would contain small integer(whole-number) input values and have relatively small integer results. Colt licensees would be required to have a general understanding of Ohm's Law and Power relations. They should be required to have a general understanding of how antenna length relates to wavelength; and have a knowledge of transmitter power, antenna gain, transmission line loss, and the ability to perform a simple ERP calculation would be required. General knowledge of simple resistive circuits, and their power dissipation, would be required. Knowledge of capacitors and inductors would not be required.

If you respond to the Colt License Proposal thread, please drop
alt.radio.family from the header. The majority of FRS users are simply
American families using these low-powered radios as short-range "intercoms".
They are not radio hobbists. Thanks.

The VE's were incorrect to ask for another fee to take the extra. That should have been covered under the one fee.

Also, the VE group can keep a part of the fee, but only enough to cover their expenses. Their time cannot be charged. The rules did just change on keeping records of expenses incurred.

Oh nooooooooo....NOT again!

Stewart, I think this "new" license class was the RESULT of one
too many "Colt's".....Colt 45 Laager's, that is......

The FCC MAY assign another RM, but I bet a Happy Meal that they
just say "Been There, Done That".....

They just got done paring down the number of classes...They did
NOT do that just to make room for NEW licenses.

There are already NUMEROUS stories of YOUNG kids (7-8-9) passing
the PRESENT Technician license, so I really doubt they will predisposed
to creating something "new".

If you REALLY want to make an impact on kids in Amateur Radio, try
writing a text FOR kids...THAT will help them along the way. Trying to
wrangle a "new" Amateur Radio license out of the FCC for posterity's
sake isn't it.

The Technician Class license is so easy to get now it's not even funny. You
sure you are not being a little jaded in your view when you think every kid
wants to work DX on H.F., hence starting out on CB Radio shooting skip?

According to the ARRL VE Manual , Eith Ed. , 2000, p. 50,
under "Retesting,"
"An applicant who fails an element at an ARRL/VEC-coordinated session
may retake that element at the same session, if (1) the administering
VE team has a different version of that element, which the applicant
hasn't taken (section 97.509), (2) the VE team has the time and
resources and is willing to readminister the additional version; and
(3) the applicant pays an ADDITIONAL (emphasis mine) TEST FEE (because
the candidate is then considered a walk-in candidate who just arrived,
even if he or she arrived at the beginning of the session). Again, a
retest fee charge is only required if an element is retaken, after
being failed at your session."

The W5YI VE manual has the same thing .

The reimbursement fee (test fee) is the only fee that may be charged at
a test session. Now, if the test session occurs at a hamfest,
instruction class, or other gathering, an admission fee may be charged
and it has to be kept seperate from the test fee. If you're just going
to the test sesion at a hamfest, you shouldn't be charged a fee.

Hi Bill,
Modeling shows a best VSWR of 1.6 assuming the center is at 30' also. But allowing for a few feet of droop to the center puts the VSWR right at 2:1- so all is as it should be.
Put the center at 40' or so to get a 1:1. Of course the difference in efficiency between a 1:1 and a 2:1 would be difficult to see on the air.

Tom,

You may want to investigate building a quagi. You can find info via a search engine. This would be easy to build because you could use a wooden boom and almost any kind of wire or tubing for the elements. I think the big plus would be not having to make any kind of matching device.

Does anyone have experience with the B&W HF
wire antennas the work all of the amatuer bands
without a tuner.

How do these antennas perform?

Thanks

1520. Cleaning Roller Inductor

Newsgroup: rec.radio.amateur.antenna

I have a C-L-C type antenna tuner that the roller inductor was somewhat eratic. I took it apart and cleaned all the contact points with some freon type degreaser and it worked great but the roller inductor squeaked when turned. Then I used some spray TV tuner cleaner/lubricant and the squeaking stopped but when I tarnsmitted on 17m there was an oil like smell from the tuner indicating that the TV tuner spray did not like high current. So now I went back to the squeaking mode. What should I have used to clean the roller inductor with?

73,
Larry Benko, W0QE

I personally know an eleven-year-old Extra. 20-wpm-code-test Extra, at
that. He was 10 when he passed the 20wpm. He was 8, IIRC, when he
passed the Tech exam.

Sounds believable to me. My 10 and 11 YOs are studying. They want to
pass the 5 WPM in time for field day.

Hey, why don't we just finger print them and give them a license. If a
young person cannot pass the tech exams today they are:

1. really NOT that interested in radio anyway
2. retarded and illiterate (I know lots of extras that fall into that
category)
3. Wanting to simply sign on dotted line for radio frequencies access.
(To my knowledge this is still a violation of ITU standards)

There are five and six year olds who have passed the EXTRA class test.
That's how easy it is to pass a ham exam with very relaxed exam
requirements.

If it's not receiving well, sounds like a coax or connector problem. The SWR of a 80m dipole is not going to effect the receiving qualities of a 80m dipole. Or maybe you are coupling to other wires. If you check the caox and connectors and end up ok, shift the center point of the dipole to get a good match. IE: take a bit off one end and add to the other. You will have to try it to see which end you add to works the best. But I think you have a problem somewhere with connections or coupling with other wires. It is not normal to show a high SWR on a fairly low 80m dipole. Should be fairly low if it's cut right, and no coupling to other wires. MK

Billy,

You didn't say whether you were measuring the SWR at the antenna (at the center), or at the end of your feedline (at your tuner/rig). Your feedline can be influencing the SWR reading. Along that line, are you using coax or a twin-lead for a feedline? -- and, how long is your feedline: 1/8, 1/4, 1/2 wavelength of 80m (adjusted for the velocity factor (VF) of your feedline (VF=.66 for most coax)) -- or a random length? My dipoles work best when I cut them to 1/2 wavelength (adjusted for VF).

Schulk

Billy,

Sorry, but I may have "mis-spoken" when I said in my last message that I use a 1/2 wavelength coax for my transmission lines. It's been a year, so it may be 1/4, instead -- I'll have to look at my notes when I get a chance. However, I'll bet somebody else can tell you faster that I can find my notes!

Also, I seem to remember that the SWR read-out itself may not be influenced by the length of your feedline, but the impedance, which can affect your receiving, and your RFI on transmit.

Are you using a tuner, or just a SWR meter?

Texas Radio Products (http://www.texasradioproducts.com) sells a Texas Bugcatcher for $150, or less than half what GLA Systems charges.

Is the version from Texas Radio Products any good, or is it just a cheap imitation that doesn't work?

Can't afford them right now as handy as they would be for our charity bike rides that we like to do (got into that through the ham club). Between them and their 3 brothers, it's tricky just trying to keep them in bikes plus save up for a an extra pair of 2M rigs and eventually an HF rig. Luckily they do neighborhood handywork and pay for half of their own hobby stuff, otherwise I'd never be able to afford it.

You can see them at http://www.tfn.net/~gfloyd7/cmn/

I'll bet every one of those five and six year olds have an IQ in
excess of 120 and you certainly cannot say that for every adult ham.

They say it is an air core coil but it isn't 100%. Find out what that
"protective tube" is made out of before you decide to buy. I wouldn't
buy it if that "protective tube" is made out of PVC.

They do neigborhood handywork? Man - now that is really a dying breed.

I remember I used to have a paper route when I was a kid. Nowadays the
newspapers are all delivered by adults in cars, because(I assume) there
aren't enough kids that are interested in doing it anymore.

As much as I respect your kid's work ethic, the reality is that in
today's society, the notion of having to actually work for something
has been virtually lost. I'm attempting to return to some kind

of "reward for work" ethic that reflects today's reality. The thing is - most kids aren't interested in getting on HF nowadays - because they can just get on the telephone or Internet and communicate more reliably around the world. Also, kids want to be able to communicate with their own peers(who have the same general interests). The idea is to create a critical mass of kids to make the whole thing feasible - provide a big enough carrot, and a small enough hill to climb to get to it. Obviously, we shouldn't just let anyone on who just signs their name on a piece of paper; but requiring all youngsters to have to learn about inductors is a little bit overboard, when all they want to start out with is to learn to communicate a little further than their 500mW fixed-antenna UHF rigs allow them. I want to teach them the right way to get there, and give them enough rewards that they are going to want to learn the right way to get there. This is an entryway to the Service - hopefully many will go on to get their Technician and higher licences.

I think MURS could be somewhat of a help in getting kids educated about radios - but the fastest digital speed possible on MURS will be about 4800bps(in reality 1200bps). This is not enough of an incentive. 19,200bps can be cheaply and easily done on the 1.25m/70cm ham bands, and I think that would be a VERY big incentive.

Even at Georgia Tech they must teach that changing an impedance changes SWR.
8>)

As a half wave repeats the termination, it is probably what you wanted.

That being said, it don't matter...

Hi Folks,

Can you point me in the direction for horizontal extender poles? IOW's If I have a pole with a 2 meter and I want to add other antennas but set out from the main pole. Sure as heck I have the venacular wrong for this message but I think you know what I am asking for. Or some plans to make my own.

Thanks

I suppose you didn't take the Novice exam seriously either, eh? The last version(intended to be used up to June, 2001!) contained no mention of inductors, and contained zero questions that involved a correct answer involving a capacitor.

Also, please note that this new "Novice" license does not involve any HF privileges - where the possibility of widespread interference was a possibility.

This sounds like a right wing, jackbooted, Nazi attempt to make someone work to obtain a license. We can not allow this to happen!

We should issue a license to anyone who shows an interest.

We need to be sensitive to the desires of today's youth. Are none of you able to fathom the deep loss to a young persons self esteem were they to try and fail for what ever reason.

Only a group of insensitive old hams that want to feel superior because they expended some amount of effort is keeping this from reality.

As of today I am forming NHI (No Hassle International) A group dedicated to remove the artificial barriers keeping young people from what they have a "right" to and deserve.

To fight this fight against the narrow minded ego driven old hams that are holding us down will require substantial funds.

Please send $10, $20, or what ever you can afford to my address as listed on QRZ. You can be sure the money will be put to the best possible use as determined by the Board of Directors of NHI. (Me)

Yours to rid the bands of any incentives

My kids love the idea of HF...they've talked on sideband on CB at a
friend's house before and thought that was really neat. Maybe one of
these days, you'll hear them down there, but it will probably be on CW
because they are fascinated by the code.

Get yourself a length of 2" OD aluminum tubing and attach it horizontally to your mast with either a store bought or home made u-bolt mast mounting plate like those used on any yagi...

(I tried posting this before, but I don't think it made it

I'm putting up an 80 meter dipole with ladder line as the feed.

Because the shack is on the other side, I have to route it around the outside of the house.

Does anybody have a solution as to what kind of stand-off will work well. Everything I can think of would put metal close to the feeder.

Somebody must have solved this!

Thanks.

> young technical minds are being taught properly.

Sounds good to me. Teach a class, donate some books and/or equipment,
set up a demo, make Field Day more of a family picnic/radio demo thing.
Works for me.

I disagree. It's easier. Instead of two exams totalling 65 questions
there is now just one totalling 35 questions. Almost no theory at all.

How, with such rigid limits and simple tests? You think they are gonna
build radios?

>
> 4) Take advantage of the success of the Family Radio Service, and
provide a
> path for those young users interested in further radio
experimentation.

FRS is a success because you don't need to know anything about radio to
use it.
>
> The Colt license exam would consist of 25 fairly simple questions.

The Tech is only 35.

>Emphasis
> would be put on understanding the existing operational, safety,
etiquette

and
> their power dissipation, would be required.

That's a lot more than the current Tech requires. Try one, and
intentionally get all the questions requiring math wrong and see how
you do.

> Knowledge of capacitors and
> inductors would not be required.

Why not?

It's pointless, Stew. Young people will be drawn to ham radio by the
challenge, not by being spoonfed and treated like they are helpless
babies.

1546. Follow the Money

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-19 22:17:17 UTC
From: K0HB <K0HB@arrl.org>
Message-ID: <94aed5$8mn$1@nnrp1.deja.com>
Source record: 171822
Cross-posted to: rec.radio.amateur.policy,rec.radio.amateur.antenna,alt.radio.family,rec.radio.cb

When you don't understand why somebody is doing something which seems senseless to you, sometimes it pays to try to "follow the money".

In this case it led me to a company called "PubCel". According to their web site, that company is involved in:

"Wireless Entertainment and Communications Solutions:

- MURS and ARS Voice and Data Communications Systems

- FRS and GMRS Voice Communication Systems"

I think it is safe to say that the "ARS" acronym might mean "Amateur Radio Service".

Also according to their web site, the company President is none other than Stewart Teaze, N0MHS.

Suddenly this proposal for the "Barbie Doll" Amateur Radio license isn't quite so senseless.

73, Hans, K0HB

Sarcasm noted, Fred. I'm not trying to produce a giveaway license -
but I am trying to forge a modern replacement to the lost Novice Class
license.

Maybe the right idea is to just call this class Novice, and call all
existing Novice Class operators "Novice Plus" - where "Plus" indicates
plus HF, as it does with the similarly closed Technician Plus class.
Novice Pluses would also pick up the extra sliver of privileges on 70cm.

This is for Ham radio. ATV ans SSTV if it's a good day. If you're cheap enough NOT to have cable which by the way will be MUCH cheaper installed than a freaking aerial, you not only don't belong here, but you're a cheapskate. Now if you're looking for an indoor TV transmission antenna, you're just plain stupid.

Source record: 171834
Cross-posted to: rec.radio.amateur.antenna,uk.radio.amateur

I'm looking for construction details for a remote-controlled antenna tuner
that will work with an end-fed antenna. Quite possibly it is dedicated to
work with such an antenna. (For non UK folks: I'm in UK, but perhaps that
fact won't make much difference (I'm on 240v AC)). It would be good if
the ATU was capable of handling 400W PEP. But in the early days I will
be using about 150 Watts RF out, so any ATU that was suitable for
that level of output would be looked at.

(Has anyone in UK one for sale?)

Thank you.

Rich.

From: Jerry Oxendine <joxendi@bellsouth.net>
Message-ID: <3A68DB2C.7615@bellsouth.net>
Source record: 171833

I build a version of the popular Screwdriver antennas that, I believe are superior in a couple of ways. Instead of the 1 1/2" coil wound with #16 wire, my coils are 2" or 3", depending on model, and are wound with #14 wire spaced to give maximum efficiency. There is NO PVC used in any operating/radiating portion of the system. If you are considering the purchase of a screwdriver for your mobile, please contact me via email for pics and prices.

I've never tried to hide the fact that I'm trying to create a
business. Quite the opposite - why would I list the web site on the
signature to all my posts, if I was trying to hide something

Hey, Hans, I wonder why you switched your approach to this slimly
veiled "personal attack"? It couldn't be that I was right about the
point regarding inductors and capacitors on the Novice test, could it?

Let's stick to the point at hand. You made a good point about the lack
of digital modes in the proposal - THIS is the kind of stuff I'm
looking for.

Not true. MURS allows external antennas and digital modes. These are
big differences over simple FRS.

If ARS is to "compete" with MURS, we are going to have to come up with
something new.

Some of us have more experience in that than others, I guess. :-)

Those who use the MURS radios will learn something in the process. First, the radio has a range. They will learn that buildings and obstructions limit that range. They will learn that the range is farther if you are at the top of the building than if you are in a valley.

I think a better analogy that the porn chat room (where did you dig that one up) would be to ask what education has been the result of giving kids internet access in general? As a big kid, I can't begin to describe how much I learned that way.

> You turn on the box, select a channel and talk.

That is indeed most of the picture. Now, can we use the good and bad of MURS to find the subset of those kids that don't yet know they would like to be hams?

Jason,

First of all making measurements of a 20 meter antenna over a path length of a 'few blocks' means you are really measuring the near field radiation, not what you want.

Now about your questions. Your Hamstick is a full quarter wavelength on 20 meters compressed to 8 feet by winding the wire around a fiberglass pole. You attached radials to the mag mount base. The wire is a half wavelength on 20 meters. End feeding it means you have a high impedance for the feed point! Your tuner was fortunate enough to resolve the situation!

Connecting wires using wire nuts is iffy at best. What you want and need for antenna work is good solid connections, low resistance connections. The resistance added by your connections shows up in the SWR, That is probably why you saw a 2.5:1 SWR for the hamstick.

To properly compare antennas at HF you should have a way to switch between the antennas very quickly. Get them both tuned properly, and make a contact. Ask the other ham if he will mind listening when you change antennas. Do this several times over long path lengths, and you will have a better answer.

Frank,

There ae as many ideas about condo antenna as there are condos! I have used a MFJ Loop from a condo but I must say the performance was not very good. This unit was sold in competition ot the AEA Isoloop.

Perhaps it was the orientation I chose. I used the loop in the horizontal plane. Tuning was probably influenced by the close proximity of other objects like the building! I found it radiated enough energy in the near field to cause my radio, a Kenwood TS130V, to lock up at the 5 watt level! Of course in a condo there are only so many places you can put the radio and all of them are near the antenna!

Do you have any trees close to your condo? I published an article in QST for June 1995 on my condo antenna. Aside from the launching system it was a simple end fed long wire that ran out a window at my operating position to a near by tree. I used this antenna off and on for nearly 20 years, I worked all states with it an probably DXCC too. Much of the operation was at QRP levels!

Dodge,

I use plastic rain gutter brackets as window line standoffs to feed my horizontal house loop. They are sort of a 3 sided square shape (U shaped).Since use they are used to hold up rain gutters in all kinds of weather (hot and cold), as well as not deteriorate in the sun, they are an excellent, long lasting, and durable solution.

The bottom part of the U can be screwed to the house with non-rusting decking screws. The arms of the bracket have little indentations on them that I cut with a dremel tool cutoff wheel. This creates a slot in each arm that the window line can be pressed into. I alternate the bracket between the left and right side of the line to keep it secure. The brackets last, do not rust or break, and are inexpensive. As an added bonus, it is easy to pop the line out of the bracket, if needed for repair or maintenance, yet holds the line secure. They come in white or dark brown to help match house or trim colors. You can even cut one bracket in half and have two "L" shaped brackets to save more money. It sounds more complicated than it is. Just go down to any well stocked hardware store and check one out. You will see how easy to work with they are.

I looked at many and tried a few other solutions with lesser results. The biggest problem, finding a decent way to attach the standoff to the house, or a decent way to attach the wire to the standoff. Too many of the other options will rot in the sun or break in the cold. I even use these as standoffs for my horizontal house loop as the antenna wire standoffs. This gets the wire off the house, but is very stealthy.

Hope this helps.

Keith,

You would be best off if you didn't double the radial back on itself. MFJ and Ten Tec both make "ground tuners" or "Artificial Grounds". Look at them as a way to tune your ground wire to resonance. They aren't very expensive and they do work!

Using number SIX wire is OK, the most important part is that you make low resistance contacts. Tie downs made of poly are perfectly OK.

Dodge,

I also checked into electric fence insulators as standoffs. Like you, I found they all came in bright safety colors. Probably another new law there. I also found that, while easy to attach the window line to the insulator, getting the insulator on the house was problematic. They are meant to be clipped to a metal fence post, not screwed to the side of a house.

I then stumbled onto the plastic rain gutter brackets and smiled all the way home. They were easy to screw to the house, easy to slip the wire in notches cut on the arms, and work better than I had hoped. Matched the house trim too, so no painting to hassle with.

Good luck, Tracy

Source record: 171847

Michael,

In a traditional End Fed Zepp The far end of the twinlead feeder is not connected to anything. I believe the antenna wants to see 600 ohm open wire feeders.

an antenna I know much more about, is the End Fed Wire. Very similar but it has no feedline. You connect a wire as long as you can to the tuner output for a single wire. And you're in business, sort of.

My antenna here runs from a first floor window out and up to a tree that is about 50 feet above ground. Then it runs across the back yore to another tree where it runs down to about 6 feet above ground. It loads easily on all bands from 80 through 10 meters. It does need a good ground at the station end. I use an MFJ artificial ground tuner and a 15 foot piece of wire!

Stewart,

The idea has already been tried. Back about 15 or 20 years the Dutch instituted a license class for beginners. It consisted of about 5 frequencies in the two meter band. Licenses required only a simple test. No code. It was hoped that these Novices would upgrade and become regular licensees. As for as I know none ever did. The service still exists, I believe.

If you want to have youngsters or oldsters learn about radio the best way is the old Novice license. % wpm code, a simple theory test, and a one or two year limit within which they HAVE to upgrade!

The only way it might help is if they have an Elmer type to explain what is actually happening when they talk. From that standpoint, CB would be better because at least they can practice antenna and electronics theory (especially if they get busted radios donated for practice demolition er I mean repair), and there's at least a little bit of propagation that might get their attention and give them something more to learn about.

At the same time, having adult supervision would be even more necessary in case "emergency censorship" of the ongoing conversations become necessary.

This is something you can easily and accurately model with even the free
EZNEC demo program, available from http://eznec.com. I'd begin by
knocking off one element or the other from the NBS Yagi example,
fiddling the parasitic element length and/or spacing, and going from
there. Bandwidth, gain, and front/back ratio can be traded with each
other, and no one configuration will be best in all three regards.

Everybody is holding their breath until the Motorola objection to FCC's creation of MURS is settled. If that gets settled positively (Motorola's objection is set aside), then I expect many manufacters to begin making MURS radios. Prices will drop, accordingly. I expect that within a year we will see decent MURS radios in the $70-$100 range. Right now the only thing specifically available are offerings from Radio Shack in the $125 range, or the 1W Motorola Spirit single channel(9 selectable)VHF business radios(don't get the two watt version, it is not useful for MURS, as the only two MURS specific channels it supports use a 25Khz bandwidth, MURS will be using 12.5).

1580. Re: QUESTION: 18-foot wire vs. 20m Hamstick

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-20 02:30:55 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3A68F85F.64339484@eznec.com>
Source record: 171854
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.dx

I'd like to add a slightly different opinion.

A few blocks away is well into the far field. From a simple antenna like a dipole or Hamstick, the far field begins at well under a wavelength (20 meters in this case) from the antenna.

I've used wire nuts for many years to connect antenna wires, both inside and outside. If they didn't provide a low resistance connection, your house would catch fire, since they're widely used in house wiring.

Finally, I agree with the advice to switch rapidly back and forth between antennas. But instead of relying on reports from other stations, simply compare the antennas when listening. There are a number of good reasons for this. One is that you don't have any idea what size the other station's "S-Units" are. They might be anywhere from 2 to 6 dB -- a big difference. Another reason is that signals can fade from one antenna to the other, giving one an advantage at one moment, while the other will look better a couple of minutes later. By listening, you can average out these changes. And you can also do a lot more comparisons from a lot more directions, since an observation takes less time than a QSO. By listening, you can compare antennas on signals from stations you're not able to work. With a simple step attenuator, you can make decent quantitative comparisons in dB if you're so inclined -- or you can calibrate your S meter for the same purpose.

You'll probably find one antenna to be better in some directions and at some distances and the other better at the others. If one is better in all directions and at all angles, it's probably poorly matched or there's some source of loss in the system.

I originally posted to rec.radio.cb to support my argument that CB is
obviously NOT the proper environment to be starting our kids off in
radio - and you folks did not disappoint me, as the typical vulgarity
of your posts show.

Look, I don't have anything against you folks - I just don't think it
is appropriate for kids to be learning radio on the 11 meter band.

Did I mention HF at all? Nope.

The point I'm making is that young people are more than capable of passing the existing tests and being good ham operators. I know by my own experience and numerous examples like the young ham I worked. And many more. That's dead-nuts-on the subject of the discussion at hand.

From: jflanders2@home.com
Message-ID: <3a6901d4.690504114@news>
Source record: 171859

I just ran some ladder line about a hundred feet through some pine trees here. On the first 40 ft of the run, I laced a small dacron rope through the holes about 5 feet apart, tying it to the LL at each end and in the middle (at 20 feet). Then I secured this dacron rope to the trees and it supports the LL nicely. Very little dacron in the RF field. Then I used pieces of nylon twine to support the remainder of the run below the branches at several points where it runs through the trees.

Seems to work OK, and don't see any effect on the RF.

If you can pull a rope tight along your run path, either run the rope through the holes in the LL or use ty-wraps to suspend theL the rope.

For once a constructive suggestion! My 11 year old has asked me several times if I can find a ham radio technician text that is geared for young people. So far I haven't found anything. Anybody for getting something like this together? It doesn't need to talk down to the kids. Kids are bright and intelligent and can understand amazing things. But it HAS to be made interesting to THEM. If you could disguise it in a Nintendo game it would work even better. If it were available for download for a free or minimal cost so much the better. Now THAT would be a contribution!

Source record: 171861

Well Gary,
I have the 90' copper weld folded dipole. It is up at 55'. It does work pretty good on 75 through 10 meters. It has an unacceptable SWR on 160 though. I have to run a tuner to match the line on that band. It has served it's purpose here as a multiband antenna to run mostly without a tuner. I understand that the efficiency isn't the greatest, but it works ok for me. I am taking it down tomorrow, as I need to get a better antenna for 160 up. I will miss the "just tune around the dial without worrying about the swr" feature, but I need to get a real good signal on 160 right now. You can build ALOT of multiband wire antenna's for the $180 or so that I spent on the B&W dipole. I would dig around on the net and make a trip to your local building supply dealer and pick up some wire and insulators and go have a good time homebrewing. Have fun, Mike> WE0H.

Try putting ferrites on the various cables from your computer. I got rid of most of my noise this way. Especially try the keyboard cable. Sometimes you will need ferrites at both ends. There are some large split beads with 0.5 inch holes which allow you several turns of larger cables. Most split beads are in material 43 which works well, especially with several turns.

:> What gives? At 20m, why didn't the 18-foot wire antenna with HIGHER
:> power and LOWER SWR trounce the 20m Hamstick with LOWER power and
:> HIGHER SWR?

: 1. SWR doesn't tell you anything about an antenna's performance. All it
: tells you is how close the feedpoint impedance of the antenna is to the
: rig coupled to it. And since you're using a tuner, what you're measuring
: is simply the match between the tuner and the rig.

Not true. All it tells you is the ratio of the feepoint impedance of the
antenna to that of the characteristic impedance of the transmission line.

If using a tuner, and the meter is between the rig and the tuner, then
the SWR only tell you how well the tuner matches the transmission line.

The match of the rig to the transmission line is immaterial.

: the other end about 30 on a push up pole. I have nylon string that places
: it about 20' for either end with homemade PVC insulators. I'm not receiving
: well with it either. Does any one have any suggestions what the problem
: might be for my first homebrew antenna?

Let's assume that your meter is reading correctly - which may, or may not, be the actual case. I am also assuming that you are feeding the antenna with 50 ohm coax.

If you cannot get lower than 2:1 VSWR, that means that your dipole has an impedance of 100 ohms or more at resonance. That is not out of sight for a dipole mounted fairly close to the ground. It is highly unlikely that the impedance could be as low as 25 ohms - the other possibility.

There are a couple of things you can do to improve this. The first is get the dipole higher into the air. If that does not bring the SWR down enough for you, then you can lower the ends - making it an inverted V. Try to keep about a 120 degree included angle between the legs. As you make the angle more acute, you lose more and more of the directivity of the dipole.

You can also feed the antenna with 72 ohm coax - which would be a better match for a dipole that is well up in the air.

Source record: 171724

Yes. Suppose you had a very lossy piece of cable. You put power into it, but only a small fraction of that power gets to the far end. Whatever is reflected from the far end is attenuated by the same factor on the way back. So even if the far end is open or shorted, that is, all the power is reflected, very little reflected power appears at the input. So at the input you see a very good match. For example, if a cable has 3 dB of loss and is terminated in a short or open circuit, the SWR at the output will be infinite, since the reflected power equals the forward power. But the SWR at the input will be 3:1, since only 1/4 of the forward power appears coming back. A cable with 6 dB of loss (where no more than 1/16 of the forward power gets back) will never show more than 1.67:1 SWR at the input, and so forth. A long piece of coax makes a good dummy load, and at high frequencies it doesn't take a very long piece.

This is a good solution for those folks who like a quiet antenna with low SWR.

Because the losses in the RG-58 are so great that it is absorbing almost all of the reflected power before it gets to your meter - given enough length, you could leave it disconnected from the antenna and get about the same reading.

Stewart,

The Netherlands implemented a license class very close to what you propose back about 1985 or so. A communicators license intended to bring the Citizens Band under control. About 5 frequencies were set aside in the two meter band for users. A ham license was granted with no code and only a simple theory test, about adequate to determine if the on light was on! People flocked to get in on the simple ham license. The government hoped if they were really interested they would upgrade, and if they weren't they could still take advantage of the thrill of communication and not bother the others. Holland requires evidence of a ham license before you can buy a ham radio,

The result? Almost no upgrades. Those who got into it stayed there. IS that what you want for our kids?

Gary,

I'd be careful about saying they work all ham bands without using a tuner. The B&W antenna I'm familiar with is a wide spaced folded dipole type fed with twinlead. At a minimum you need a way to have a balanced feed to the antenna. You will also find widely verying SWRs on different bands without a tuner. A good tuner should be part of ANY modern station!

To add just one more snippet of info - the radiation and near fields are of equal intensity at 1/(2*Pi) or about 1/6th of a wavelength from the radiator.

At a distance of 5 wavelengths from the radiator the near field is about 30 dB weaker than the radiation field and can be ignored.

Some guy built a 2 element beam for 10 and i THINK the article for it is
available on the arrl site not sure tho. It was titled 2 on 10 i believe.
Ive seen several other articles tho on 2 element beams for 10 meters...try a
search for the same on arrl.org

At one time I had some official ladderline stand-offs -- I bought them
from Radio Works...

They were little plastic dealies: there was a raised plastic square
that fit the cut-out in the ladder line, and there was a hole in the
middle of the piece. You put a screw through the hole to hold the
piece in place. Then you snapped the ladderline in place, right over
the raised plastic square.

You might try Radio Works, Wireman and some of the other guys that
supply antenna wire and insulators -- or go with something homebrew...
a perusal of your hardware store might turn up something useful...

Amateur Radio is not intended as competition to MURS, FRS, GMRS, CB,
MARS, or any other radio service. And creating a new "Barbie Doll
Radio Service" distinctly segregated from mainstream Amateur Radio
will ultimately be damaging to Amateur Radio.

It is entirely possible, and true in this case, that the real part of the
impedance is close to 25 ohm.

Roy (www.eznec.com) has generously provided a demo version of his program that
is entirely adequate for modeling this situation and ending the seemingly
endless speculation about what is going on.

The spacing depends on what parameter you want to optimize for.
What is most important to you - feedpoint impedance, gain, front-
to-back ratio, bandwidth, ...? 0.2WL gives you close to a 50 ohm
radiation resistance.

>
>Thanks,
>Max

Max, you didn't say what sizwe loop and frequency? Sure, the size and frequency don't matter, technically, to the feed technique, but at HF, some things might make one stunt attractive.

You can use a shunt feed section to match a coax feed line directly to the loop. Simply start at any point and extend, on HF on 40, say a six inch ladder line out about seven feet parallel with the loop wire. That's the gamma section. Of course, you tie one end to the loop wire. The other 'free' end becomes the attach point for, say a 100pf variable cap, in series with the center conductor for your coax. Tie the shield of the coax to the loop wire itself at that point.

If you use a Kerney (Split bolt!) connector at that far end to fasten the gamma to the loop wire, you can simply slide it in an out to shorten or lengthen the gamma segment. You adjust the cap and that for minimum reflected power on the line. Once the capacitance is known and it's all perfect where you want it, you can substitute a short length of RG-8 used as a capacitor, for the variable cap. Tie the shield to one side, and the center conductor to the other at one end. Let the other end hang free. Make it a little longer than needed. Strip a bit away from the shield at the far end. Coil it up for test until it's just right as part of the work. Trim it shorter until minimum SWR then tape the far end. No more feed problems for years if nothing changes.

About three feet or so of RG-8 is about right to start with for the final work on 40 meters, for example.

You can scale these values for 80, 160, or 20 meters and so on.

As another hint at HF loops, where you feed this thing, break the loop wire with a common antanna insulator. But bridge it with a hard single conductor #14 bare copper wire with a little three or four turn coil in it made from wrapping the wire around a small screwdriver handle, for example. Then, using that little probe coil, you can poke a grid dip oscillator into that little coupling coil! Presto, instant way to

adjust the size of the loop for reasonance! It you use this same Kerney connector as a clamp for the wire at that point, you can shorten or lengthen the loop wire to get it exactly on frequency for the desired target.

As well, since the coax end isn't wire connected to anything for DC, if you use this kind of feed, you can carry or AC voltage up the cable on the coax to the end. The use of a small RF choke at that point can get you signal voltage to control a relay. It can be used to move element lengths between two values. That can let you adjust a low band array between the CW and phone sections of the band, if needed...

Of course all this is, in practice, much different if the band in question is up on 440 or such! Maybe this was wasted suggestion for you!

--> Sleep well; OS2's still awake! ;)

Bill Nelson wrote:
"I did not imply that." (Electronics is not outdated, said Cecil.)

We have amateur allocations in the radio spectrum because amateur radio predates allocations.

Allocations became law because the importance of radio to safety and commerce emerged, and regulation was imposed to preserve the utility of radio.

Amateurs were considered beneficial to radio development and operator training. Training was not trivial. Public familiarity with electrical phenomena and the Morse code needed to use radio did not abound. Radio expertise was needed to exploit the new communications medium and was not obtained overnight. Amateur radio was a training ground for military and commercial operators. This satisfied a public need. Amateur radio also provided emergency communications for disconnected and remote sites.

The needs above are almost gone. Morse operators aren`t used by the military and industry anymore. Extra ears aren`t needed to listen for Morse SOS signals. A pool of ready-trained Morse operators to call upon tn times of national emergency is not needed.

Why should amateurs continue to take spectrum space that could be used for beneficial business and industry radios?

Amateur radio spectrum should continue to be allocated for the life, liberty, and pursuit of happiness of as many people as possible. Public lands are set aside for parks and recreation. These are non-commercial oases, as are amateur bands.

Yet another public benefit derives from amateur bands. Amateur experimenters have an opportunity to advance on-the-air communications arts and sciences.

Cecil implied that while Morse is outdated, electronics is not outdated. So, hams still need bands.

Best regards, Richard Harrison, KB5WZI

Source record: 171748

I bought a Black & Decker "edger" (about $60, IIRC) that does a good job. It cuts a narrow slit about 2" deep and usually throws small rocks out of the way. If you have lots of small rocks (like I do), the cutting is a little messy, but it works. After cutting the slit, I work the radial wire into it with a broad screw driver. A 60' radial takes about 20 minutes to complete. (I am thinking about placing two wires in the slit for my next antenna --- one being the coated, soft-drawn copper wire I usually use, and the second being a shorter insulated wire scavenged from multiconductor communications cables.) After placing the wire(s), I stamp down the ground, water it, and let nature repair the damage. After a few weeks, all signs are usually gone.

I have several dishes for sale.
The biggest is a KLM 12 foot with solid aluminum petals, and an az-el base with controller. I'm asking $200 for it.
I have an incomplete KLM 11 foot that uses screen petals. I have the ribs, etc. but not the screen petals or the mount. Make me an offer.
I have a KLM 8 foot using screen petals and a polar mount with controller. I'm asking $150 for it.
I also have a 6 foot solid aluminum spun dish. If you are interested, it could be used with the polar mount/controller that the 8 foot dish uses. I'll sell it for $125, polar mount/controller included.
Located near San Jose, CA. I can deliver in the SF bay area.

That big resistor in the middle of them smoothes out the SWR swings pretty
well.

> I only want to do this once....

What fun is that (hi)?

Since a well-constructed small loop has very low driving resistance and uniform current distribution, why not try feeding it with a ferrite toroid core. Slip the toroid over the radiator, treating it as a single turn primary. Then, wind several turns on the form to make up a 50-Ohm secondary (you'll need to experiment with the number of secondary turns to obtain minimum SWR). I think I saw this idea first in QST as a "hint and kink", and it might provide a good alternative to a coax loop.

The information you had access to may have been stale, and never was
entirely accurate.
The class-D license did in fact give you 6 channels. You had to upgrade
within two years. THe upgrade requirement was later dropped.
After a short while the examination level was graded up quite considerably.
The license class was changed accordingly and now gives you a CW subband, an
SSB subband and an FM subband on 2 meters and on 70 centimeters.
The D-callsigns were assigned alphabetically, starting with pd0aab, then
aac, aad etc.
If you look in the callbook, you will notice that there are not many left
over. Many of the "old" names are now found under the A or C class entries
nowl
To recap: Dutch A-class is "everything" (hf, vhf and up, all modes) and
requires morse code and electronics theory. C-class is VHF and up, all
modes, requires same theory but no morse code. N-class replaces D-class (N
for Novice) and requires limited theory, gives acces to Novice subbands on
2m and 70cm.
No-code on HF has never existed in Holland, but we all know the rumours..
just have to see what happens now.

have a good one,

Rudolf

OK, rather than a bunch of old geezers sitting around casting cold water on Stewarts idea, let's look at it from the view of the intended market.

Dick and Jane, 14 years old, have "had it" with the limitations of the FRS and now are "interested in experimenting with radios". They've heard of something called "ham radio" and are investigating the entry classes.

Jane says "Here's something called the Technician class. You have to take a simple 35-question test."

Dick says "Here's something called the Colt class. You have to take a simple 25-question test from the same pool."

Dick and Jane decide to investigate further, to see what difference the 10 additional simple questions make.

Dick says "Colt gives you six simplex voice/digital channels on 446, and another six simplex voice/digital channels on 223MHz. You can even build a simple little repeater between them, as long as input and output are not on the same band."

Jane says "Technician gives you 22,243 Megahertz of spectrum on 16 bands between 50MHz and 250GHz. Holy Cow, Dick, that's millions and millions of frequencies instead of just 12."

Dick says "With a Colt license you can transmit 5 watts of power. That's a lot better than FRS!"

Jane says "5 watts is for sissies. With Technician we can transmit 1,500 watts of power!"

Dick says "Yes, but the Colt radios are cheap."

Jane says "Sure, but there are lots and lots of used radios around for Technicians, even cheaper, and your Colt radio will be basicly useless if you upgrade."

Dick says "Hey, but I could put my Colt antenna 20 feet above the house if I want."

Jane says "Big deal, Technicians have no arbitrary height limit like that; they can go as high as zoning laws allow, and even higher with conditional use permits."

Dick says "The Colt license will be a lot of other kids just like me."

Jane says "I thought we were sick of kid stuff, and wanted to experiment. The Technician license lets us talk to kids and doctors and lawyers and indian chiefs and satelites and astronauts and W1RFI even."

Dick says "Colts can use both voice and digital modes."

Jane says "Hey, with only 10 more simple questions the Technicians are allowed all of that, and other neat stuff like SSTV, FSTV, telecommand, and space communications."

Dick says "Jane, you are right. This Colt thing is really lame. I always said you were smarter than me. I could just kiss you."

Jane says "Dick, only after you pass your Technician License test, and keep your clammy paws off my double bazooka antenna."

Source record: 171766

I'm using an attic mount homebrew QFH antenna for
weather satellite APT reception.

I've decided to move the QFH from the attic to the outside,
so I'm considering my options. One of the options is to
purchase a commercial QFH. While these are quite expensive
($~250) they do come with an integral amplifier which would
certainly not hurt.

Anyone have any personal experience with any commercial suppliers?
I've only found a few for sale. The following from Norther Video
Graphics is one: http://www.nvgweather.com/page2.html

Any suggestions/comment would be appreciated.

I'm curious...Has anyone ever tried using a "good" PVC coil in that shootout? I use PVC coil forms here and haven't really noticed any bad effects. I've compared to bug catcher coil antennas and couldn't really tell much difference. Actually I won, in one case I'm thinking of, but the other antenna was a bit shorter, so not a fair test. I've never had any problems with them here so far. I use the 2-3 inch grey PVC that has no metal content. I tested by cooking in the microwave and stayed ice cold. Dunno, I've never entered the shootout yet. Maybe thats why they "pvc" haven't done well yet...g I bet mine will compare pretty well. As one test which I have done, I compared my coil to a hustler which everyone knows is kinda lossy. The hustler coil was terrible against mine, just as it would have been against a bug coil. So I don't think the difference between the two is large at all. "PVC and open". MK

The higher the cable loss, the better the swr will look. Take a 500'
piece of RG58 and leave the far end open circuited (or shorted) and
measure the VSWR at 70 cM at the other end- it will look great!

My HS-1600 uses something like phenolic. Wonder if hsantennas.com tells
what it is made of? And srewdrivers come close but rarely win 75m shootouts.

1654. All Band Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-20 22:31:43 UTC
From: motorhomer <motorhomer@my-deja.com>
Message-ID: <94d3kg$808$1@nnrp1.deja.com>
Source record: 171777

I currently use a 136' doublet fed with 450 ohm ladder line and an old Johnson Kilowatt Matchbox to tune it. It is only up about 25' at the feed point (my chimney) and it slopes down from there to within 6 feet of ground in some places. It also is bent back on itself in a few places beause it follows the contours of the house and yard. In no area is it really out in the clear. I am not very pleased with the antenna, it seems to be about 50db down from others in my geographical area on receive. I do have an amplifier that helps transmitted power but TVI is also a problem. I tried a Gap Titan but it was about equal to the doublet. I recently got a MFJ259B Analyzer and thought that I would try pruning the antenna but I wonder what others think that have been in this situation. What is more important, a higher antenna or an antenna in the clear? Does it make more sense to have a shorter antenna if you can get it higher or more in the clear? I live in a city area that frowns on antennas (CCR's) so whatever I do I must be sly. Thanks for any help/tips.

Hi Pat--

You lucky dawg! I tried to get one of those for review, and everybody at every magazine in the entire universe beat me to the punch. Poot! The 817 is still a little scarce, even if you've got the bucks waving in your hand. Hope it's everything it's cracked up to be!

Actually, I'm bi....or bi-amped I should clarify. I love QRP and have devoted a big chunk of my ham life to it--especially when working DX. But, when I ragchew on 75 SSB, nothing beats a big antenna and ugly amounts of clear-channel QRO power. Some of us just have to go to the gym and "flex" once in awhile!

Message-ID: <Mppa6.353$UX4.41725@news.goodnet.com>
Source record: 171782

I'm looking for input on the MFJ-1750 2m 5/8-wave groundplane antenna. I'm looking for something inexpensive that has a little bit of gain for use in my attic. This antenna, at $19.95, looks like it should fit the bill. Any input from anybody who may have purchased one?

Tnx & 73, Michael N9BDF

Steve,
If your talking about an 'all-band' antenna, I wouldn't
worry too much about trying to make it resonant on other
than the lowest band you plan to use. Now, that takes for
granted that you use the 'Matchbox' and the doublet on all
bands, or at least the bands the 'Matchbox' will cover.
Most verticals, no matter what/how they advertise them,
do require a good ground. If you can provide a good ground,
a vertical will work well (as well as any vertical!?).
Good luck with it...
'Doc

1660. Re: All Band Antenna

Your in a situation that so many other hams have struggled with for
countless years Steve.
The simple facts are that physical length [proportionate to wavelength] is a
far better radiator than electrical length [loading coils etc] so you're on
the RIGHT track.Your half wave [80m] fed with ladder line via a tuner is THE
most simplest and EASIEST to use of all antennas because of its harmonic
relationship to all other HF bands.
NOW, having said that,HF physical length can be monsterous as you're well
aware of.what you've already done by mounting it as high as you can etc etc
then bending it to fit is what most of us are at now,add to that the city
restrictions and you've compounded the issue.
Ive found that providing the "legs" are not closer that 60' AND are at least
6' off the ground it should work reasonably well [i fed mine with 300 ohm tv
ribbon] .
Another wire job i love is the long wire.my back yard is "LONG ENOUGH" for a
1/4 at 80m 66' etc and i gets out well.

May i suggest you've not done anything wrong but more to the point you
merely have not discoverred the BEST option for your location.
We ALL know "get it high" etc but its not practical sometimes.
Hope you solve it mate,GOD BLESS,Rod VK4XI

Hot button here. Is the 817 actually a decent radio? I don't care about the
transmitting side or how cool the carrying pouches are or the battery life, I
care about the HF receiver performance. Front end dynamic range, intermod,
crossmod, sensitivity, cw filter characteristics, internal noise, glitches, the
usual. Comments on the technical performance in receive vs.other HF xcvrs
you're familiar with?

Hi Michael
I had one of these up at 35 feet.I was able to work repeaters 35 to 45 miles away on 50 watts, and sometimes 10 or 25 watts.I also worked simplex with a friend about 40 miles away.Note also that my elevation is not that good compared to the surrounding area.I replaced the 5/8 ground plane with a Diamond CP-22E, a 2 5/8s colinear at the same location, on the same 35 feet of mast.There was an improvement, but not that much.Considering that the ground plane was $25, and the CP-22E was $69.95, I would say the MFJ 5/8 wave did very good.I still have it, and if something happens to the Diamond I 'll put the MFJ back up and forget it.It's small light and easy to get up.Good omni antenna for 2m.If you need more look at a beam.Thats my experience, and 2cents worth.Good luck with whatever you choose.

I'm surprised that a PVC covering would make a significant difference. Tom, W8JI, has pointed out that on the lower bands at least, ground loss is generally so much greater than inductor loss that it would take a pretty poor inductor to hurt things noticeably. But even at that, I wouldn't expect a PVC covering to lower the Q much, unless the Q is exceptionally high to begin with. It's certainly better than no covering at all -- I'll bet that one drop of water between two turns lowers the inductor Q a whole lot more than any PVC covering.

The 75m shootout sounds like a great way to collect data. I wonder if you could furnish a little more information. For example, has anyone with a solid copper antenna ever won a shootout? How about a silver plated one? One with a gold plated inductor? If not, I assume these are also low efficiency antennas that should be avoided?

Guys, please be careful running ladder line through trees or anything combustible, especially with a high SWR. I had some ladder line arc to a metal object just outside my window one night and it was a sight to behold. Had it been in a tree... well, use your imagination. Trees are conductive and flammable.

A word to the wise.

If you used the standard formula for a halfwave dipole and cut it to
that length, it will resonant substantially lower in frequency when
mounted close to the ground, since the standard formula is for a
halfwave dipole in free space.
Try checking it about 200 kc lower in frequency and see what the SWR
is. It should be lower. If it comes in lower, you will need to prune
some off the ends and try again, the old "cut and try" syndrome.
If it is not, I'd be looking the feedline and your coax connectors over
real close, that receive problem is usually caused by a connector/coax
problem rather than the antenna. PL259 connector installation gives lots
of problems as a single strand the braid can easily short it internally
if proper care isn't given. That antenna should receive well closer to
the ground than that.

There are some split-core ferrites in plastic cages out there that will snap over the cables, Rat Shack carries a small RG58 size version, like Roy say, a bit pricey. I've seen a half inch version that will work on RG-8 size coax or other cables at hamfests several times offered new by vendors for $2 per, the latest was last weekend at the Springfield, MO Winterfest.

Wrapping a solid copper wire around my stainless steel whip raised
my signal by about 0.3dB. The guy who won the El Paso hamfest
shootout two years ago used a two inch copper pipe for his antenna.

> How about a silver
> plated one? One with a gold plated inductor?

Only other data point is a stainless steel coil didn't do very well.

> Jason Hsu, AG4DG

Hi Jason,
Here's a nice page that deals with some of the practical aspects of 1/2 wave Verticals. http://www.geocities.com/aa5tb/efha.html

But to answer your question a half wave vertical is nothing more than a 1/2 wave long radiator mounted vertically.. It's a good general purpose antenna.. but not much better than a Quaterwave with a good ground.. Thought it is claimed that 1/2 wave verticals do not need a ground.. that really depends on how close to ground it's mounted.. just because the antenna is resonante does not mean that ground losses in the near feild do not detract from it ability to make contacts.

The old adage is still very true.. H.C.L. (High, Clear and Long) the high you can mount most any antenna the better. The more in the Clear of other objects the Better , and generally the Longer you can make a Horizontal wire the better. (this last one does not hold true for verticals.)
Long veritcal wire say much over 5/8th wave- begin to develope high angle radiation which is pretty much usless for working dx .

LET PROGRAM VARNEY STOP THE ARGUMENTS !

To numerically compare the radiating efficiency of any dipole with any other dipole, of any length, fed with or without: tuner + coax of any length + balun + openwire of any length, of any Zo, of any wire diameter, at any height, at any frequency.

Program also provides the long sought-after resonant frequencies and feedline SWR's of any dipole - including the world-famous or infamous G5RV.

Will also provide you with L and C component settings of an L-network tuner to match input Z of feedline to 50 ohms.

Download in just a few seconds program VARNEY.exe from the website below.
Not zipped up. Run immediately

You shouldn't be using either. RG-213 is a better
version of RG-8. LMR-400 is equivalent to
9913 and does not suffer from the 9913's moisture
problems.

My favorite dealer is:
http://www.davisrf.com

Be sure to read the information on non-contaminating
jackets.

FOR SALE BY STEVE, N1IBC
80' Rohn SSV series, free standing, galvanized tower.
It consists of the following sections from
bottom to top:
Section 1: N6 This section measures 4'6" across the face, at the base.
Section 2: N5
Section 3: N4
Section 4: N3 This section measures 22" across the face, at the base.

This tower is in 20' sections and is in great shape and very rugged. It
also includes a side bracket to mount an antenna on the side of the
tower,
and hardware. $1400.00. obo

I totally agree. Don't take the negative feedback here as what the
general ham population, or the FCC really wants. Remember - most of
these folks were against lowering the CW requirements. They are still
in the "block all change' mode.

Steve,
I don't know how you determined your system is 50 dB worse than others,
but that is one helluva lot, and probably not due to the antenna alone.
Try the Gap Titan with a different radio, a different transmission line,
and without the tuner, just to make sure those aren't the problem. It
also could be an external noise source. Check the posts submitted by
VE3TMT who identified noise sources in his house. A noise source could
also be outside your house, on a power line for example. Good luck.

Message-ID: <94f2nb$l8h$1@nnrp1.deja.com>
Source record: 171813

I use the antenna for all bands 80-10Meters. When I say 50 db down I was thinking about 20 and 15 meters primarily. I am about 50 db down on these bands
compared to others in my area. Maybe my meter is incorrect. I will be listening
to a QSO and the person in my area will give the other operator a 30 over
report and I will only receive him with a S6 or so. I know that the antenna will
not play like the beams on towers which is probably what I am comparing it to. I
am just looking for more ideas on how to get a better signal in and out.

Thanks for any info

Source record: 171812

Hi Bill--

As one well-known antenna guru profered recently in the pages of QST, transmitting weaker signals seriously detracts from one's psychological ability to enjoy ham radio. To prove it, the author presented copius statistics and graphic evidence to support his claim.

Needless to say, I was profoundly shattered by this finding (but, if Dean Straw approved the manuscript and the League published it, it HAD to be a fact)!

As a consequence, I immediately returned my coveted QRP Hall of Fame plaque to ARCI along with a sharply worded letter critical of their efforts to mislead so many with bogus claims that QRP might be fun and have merrit! Moreover, in keeping with the spirit of this newgroup, I initiated a $20-million dollar civil suit against QRP ARCI for psychological damages! Using the irrefutable data and statistical evidence presented in the QST article (and with full support from the League's legal team), I won my case easily!

With my share of the proceeds (about 4% after legal fees and taxes), I bought new antennas and coax, had a 200-Amp entrance installed, bought several Henry 4Ks off E-Bay, and built a water-cooled power combiner.

The rest is history. Currently, I have the smug satisfaction of knowing I can work whoever I want whenever I want--and blow off anyone with 20 kHz who tries to bother me. Need I add that my psycholgical self-esteem is flying high and I literally radiate self confidence! Special thanks to QST for empowering me to restore my mental health!

I personally agree with holding on to the traditions. Instead of lowering the requirements to make it easier to get in, we should be making better study materials to make it easier to learn. No sense dumbing down. I'd love to write something like this myself, but just don't feel like I could doa good enough job on it to do itthe justice that it deserves.

1693. FS: dual roller inductors

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-21 17:26:46 UTC
From: k9sqg@aol.com
Message-ID: <20010121122646.15621.00000615@ng-bd1.aol.com>
Source record: 171818

Have an assembly that consists of two roller inductors, perfect for a double balanced tuner. While an individual coil might not handle legal limit, the fact that these are in a high impedance circuit means that they don't have to handle as much current. How much they could handle, I'm not sure. The RF parts are silver plated, no burns or arcs, the coil forms are ceramic, and the frame and gears are bakelite I believe, so there is no stray capacity to worry about. If you need more info as to sizes, number of turns in the coils, etc. feel free to email me.

Thanks for reading the posting.

73s,

Evan

There is a point here, at least for me. QRP is vy fb OM. In years long past while single and living in rented room environments I had 10 W and 20 W xmtrs with makeshift dipoles, etc.

It was OK for a while, but I found it rather tiresome and frustrating at some point.

Since then I have had no interest in QRP. It's strictly a personal thing. These days QRO is sort of politically incorrect, in some circles. I couldn't care less about that. I like my four Svetlana 811A tubes glowing slightly red. Often I run barefoot 100 W.

If I were more dedicated to operating, I could hunker down and sweat it out like a true QRP guy, I suppose. That is not my kind of game.

On my coils I use the PVC as a form rather than a covering. I cover them
with vinyl tape usually to keep water out. Maybe thats why I haven't
seen the problems they speak of. My coils look kinda like a section of a
hamstick except 2-3 inches dia. when viewed from the outside. MK

The PVC pipe is the internal support for the coil which is still
exposed. I'll bet a drop of water clings to PVC better than
to empty air. :-) Bugs smash against the PVC and just stay
there shorting turns while the wind is likely to blow away
small bugs hitting an air-core bugcatcher coil.

Sounds like it's acting as a high angle radiator on the high bands. I noticed this problem using a LL fed 80 m dipole camping one time. I tried the antenna on 10m and it was the pits. I think you are seeing about the same problem. Can you string up a 2nd 20 meter dipole somewhere? I bet you would see a big difference on 20m using a 1/2 wl compared to the 80m dipole. On 10m , as far as I'm concerned a good elevated vertical is the best way to go if you can't use a beam. I've never really liked dipoles on that band too much. With the vertical on 10m, your local coverage will be much better, and dx good too without wasting power at high angles. A cb antenna will work fine. I use a homebrew 1/2 wl vertical here at the moment for 10m. It's only 20 ft up, and does ok. BTW, if you did put up a 2nd 20m dipole, if you also fed it with LL,it would work ok on 15-12-10m. I bet better than the 80m antenna. Actually a 30m dipole fed with LL will do a good job on all the high bands. Would be a EDZ on 12m. Has a bit of gain. A 20m dipole about the same, except on 10m, you would have two half waves in phase. MK

Source record: 171677

After working QRP for about 20 years I broke down and bought a new HF rig. Capable of 100 watts out. It was a real hoot for a year. Now I am back to QRP and still like it. The fact is I switch back and forth depending on my own whims and band conditions. There are some real lessons to be learned while operating QRP. I believe my operating skill is higher and I appreciate the fact that 100 watts is seldom needed for solid contacts, this includes DX. I am never short of amazed at how good a signal report I can get with 5 watts and my simple ground mounted vertical. The biggest problem I encounter while operating QRP is holding the frequency because of someone running much more power than is needed is interfering. If we all kept to the basic rule of only using the power needed for a good contact we would all be better off. As the solar cycle runs down I am sure the amount of power I use for good contacts will go up. I am also sure that when conditions improve during the next cycle my power will be cut back. Simple, isn't it?

Rod,
I sympathyse with you and have been there in the same dilema for years. My experience with the other good options suggested here, by others leads me to suggest the following: 1) a loop antenna with a 80m wire, stub . Raise it as high as you can, but 10 ' will work. 2) Use an inverted vee, it takes only one line into a tree, and at a 45 degree angle, maximizes the yard length available. Your multi band antenna is ok, but is a tvi generator. The simple coax feed of a inv-vee , and use of your tuner extends the usefull bandwidth seems ideal for your situation.

Hi Bill--

>If I were more dedicated to operating, I could hunker down and sweat it out like a
true QRP guy, I suppose. That is not my kind of game.<

There's a tremendous network of entusiastic operators and builders who make up the modern QRP movement. And, although I'm rarely accused of being politically correct, I am proud to be counted as a "QRP" guy.

But, moderation in all things. At day's end, when I mix up a cold martini and settle down on 75 meters to shoot the bull with friends I've known since I was a kid, that extra 20-dB looks pretty good--and that 3-500Z contributes nicely to the glow.

73 and cheers

It works great for me. I use it on my car. First I had it with a permanent mount then later with a mag-mount. Both worked great. I rarely used over 1-watt on my HT and always hit the repeaters full-quieting. You will need to come up with a ground plane system for your attic. Maybe a piece of sheet metal hooked to the ground wire in a nearby 3-prong outlet.

The ARRL Antenna Book has a small piece about an antenna which might help you, try a vertical 30 feet long if you can manage it with several radials, one will do if that's all you can manage. if you can mount it two or three meters above ground then do so. Feed this with 450Ohm ribon feeder NOT coax and bring the feeder back to the shack and use a manual tuner with a balanced output. This type of antenna will give a good account of itself on all bands 40M to 10M and will work reasonably on 80M. If you cannot use 30 feet of vertical then 20 feet will work 40 - 10M. I have used this antenna in a similar situation except that my yard was 18feet and hemmed in by a three storey house and I worked loads of DX with it, even VK on 40M. I used an old CB antenna, don't forget to take out the matching coil in the bottom if you use one.

Just ask if you want any more help and let me know how you get on.

Fellow hams

I'd like to buy an antenna/SWR analyzer. Each having pro's and con's (price, liability, accuracy, availability in Belgium...).

Contestants are:

1. MFJ-259
(http://www.mfjenterprises.com/analyzers/mfj259.html)

2. Autek VA1 Vector RS analyst (http://www.autekresearch.com/va1.htm)

3. AEA Via analyzer
(http://www.aea-wireless.com/via.htm)

I think the AEA has the best possibilities but is pretty expensive. The Autek is the cheapest but I cannot find a reseller for Belgium. The MFJ is somewhere in between and less interesting (pay less and get the Autek, pay more and get the AEA).

My questions for you are:
a) who's got what kind of experience with these tools?
b) what is your advice?
c) where to find it in Belgium or around?

All input is appreciated!
Thanks and 73's
Franki ON4CLN

1: split beads and split ferrite filters are available from several places. If nothing else snap a core into two pieces, and hold them around the cable ,with tape, joined together. All cables leaving the computer should have a filter. Same for the cables to the radio.
2: put a star washer under each screw holding the cabinets together on both the computer and the radio.
3: I have had some success by placing a grounded piece of metal under a thin piece of plastic on the computer and radio tables, grounding these. Aluminum foil will do.
4: keep trying.

The only problem with QRP is that you put the onus on the person at the other end to dig YOUR signal out of the noise for YOUR enjoyment.

I would NOT order from http://bytemark.com/amidon/ if I were you. I placed an order with them about 3 weeks ago and still haven't received my torriods. Called them 3 times about my order, the sales guy says he will call back but never returns my call. Later I saw mail on the net that Bytemark had gone out of biz not long ago and their 800 number had quit working.

Had to go to other sources like Fair-Rite and MicroMetals for them. I called my credit card company and they say ByteMark has not charged

Exactly. QRP awards should go to the RECEIVING station. QRPers love to brag about their superior operating practices, etc, etc. Bull. They don't do anything the rest of us don't do, they just do it longer. I give 'em credit for persistence (or is it stubbornness?) but that's all.

Then why are you posting it here?

> Remember - most of
>these folks were against lowering the CW requirements.

Nope.

You have posted this same basic idea several times, Stew, with minor variations. Hams with all different views have united in telling you the basic idea is flawed. Now you're pestering the cb and FRS groups with it, even though they keep telling you they're not interested.

> They are still
>in the "block all change' mode.

They are in a "reality" mode. They are against it because it's not a good idea, period.

I have repeatedly suggested that you take a look at the current Tech test. Have you?

I took a few practice Technician tests at the QRZ website. Almost no theory questions - most of it is regs and safety. Common sense stuff, most of it. Nothing a 9 or 10 year old couldn't pass easily with a bit of study. That doesn't mean that any 9 or 10 year old will master all of the material on the test, just that they can learn more than enough to pass.

It isn't the tests. Not by a long shot.

Know why the old Novice was shut down? Because almost nobody was getting one anymore. Prospective hams looked at the privileges of the Novice vs. the Tech and Tech plus and said "I'll go for the Tech or Tech Plus, it's not that much harder". This happened BEFORE the Tech lost its code test in 1991.

Look at the recent restructuring NPRM and the R&O to see what the FCC thinks. They want fewer license classes, not more. They want simpler regs, not more complex ones. They want a more unified amateur radio. And they want to attract the CB and freeband folks, because it's easier to enforce the rules on licensed people than on unlicensed ones. The last thing the FCC wants is another license class like the one you propose.

ARRL pushed for something similar eleven years ago - a sort of VHF Novice, centered on 220. Lots more privileges than you propose, though. The FCC said no

deal and just dropped the Tech code test.

The very name "Colt" is condescending to the very people it's supposed to attract.
The real solution is more publicity and better training materials. And a realization that most young people just aren't interested in radio as a hobby. The few who are interested don't want to be talked down to and hamstrung with dumb stuff like antenna height limitations and 5 watts of power.

I don't know if there are any shootouts since Jessie quit. I tried to
get something started in the New Mexico, West Texas, Arizona area
but a lack of participation and an excess of negativity by non
participants has considerably reduced my interest. If I ever get
around to putting the equipment on Ebay I'll post a notice.

I have one of the Texas Radio Bugcatcher antennas but I don't
have an air code 2" coil to compare it to. Since coil diameter
dominates over core material with most reasonable coil
form substances I don't think a comparison is relevant.

From: motorhomer <motorhomer@my-deja.com>
Message-ID: <94gaprliq1@nnrp1.deja.com>
Source record: 171694

I took some redings with my MFJ259B Analyzer today. The antenna
is:

Resonant at 2.5775Mhz
SWR 3.0
R=14
X=7

3.8Mhz
All readings were out of range
SWR greater than 25
X greater than 600

7.25Mhz
SWR= 13.5
R=58
X=230

14.3
SWR=20.2
R=32
X=216

28.5
SWR=2.5
R=115
X=38

I did not figure out if the impedance was resistive or capacitive but I
can go back and check it out. Does anybody have any suggestions on
whether it would make sense to adjust the antenna in any way? I am
guessing that the resonance at 2.5 Mhz is due to the length of the
ladder line. Would the high impedence at 15 meters cause that band to
sound flat? The signals seem to be way down on 20 and 15 meters. Thanks
for any help.

How did you make the measurements? The MFJ characterizes everything at 50 ohms. did you put a 4:1 balun between the meter and the ladder line. I am also curious as to your definition of resonance if the r=14 and the x=7

Did you use a grid dipper or what? The values seem about right for a ladder fed dipole, Are you using a tuner between the radio and the antenna?

Message-ID: <ncPa6.103589$JT5.3630888@news20.bellglobal.com>
Source record: 171697

Nearly got my loop finished, but I am a little confused on the coupling method. All I have to go by are crude drawings and pictures too far out to actually see what the coupling method looks like. Can someone explain it to me in a step by step way as far as how to prepare the coupling loop?

a. at the loose end of the coax, do I solder the center conductor and braid to the braid at the start of the loop? or just the braid itslef and leave the center conductor not touching?

b. at the top of the coupling loop is the braid supposed to be cut and the center conductor soldered to it?

I have seen many drawings but I am getting lost in the directions, anyone actually make one of these things work?

1724. Re: All Band Antenna

Source record: 171698

I could be wrong on this, but if resonance is the point where reactance
is zero, and all is left is the resistance, if the MFJ 259B is read at
the points where x=0, the frequency will be the resonant freq and the
impedance at that freq will be the resistive part. If it is not 50 ohms,
the meter will give an swr reading of other than 1.
Am I right here, or way off the mark on this. I have one of these
meters, use it from time to time.
any comments welcome, tia
kc6ufe

Sheesh! Does going QRP mean you have to have a crappy antenna too?
Schiller's article talked about a relationship between antenna gain
(not tx power) and fun. I believe that this relationship is
undisturbed by the amount of transmitter power you inject into the
antenna. This weekend I had lots of fun in the NAQP and I never
turned my amplifier on. Just barefoot - in fact even that was turned
down to 100 watts output. I probably could have gotten by just fine
at five watts too. But the antenna was the stack pictured in the
above cited article. hehe. Take it from me - a good antenna is
DEFINITELY more fun! But, hey, that's what this news group is all
about - better antennas, right?

I wind mine with insulated wire, and then cover with vinyl. I have seen a few bugs caked against the coil at times, but have never made a noticable effect on performance or swr. Also have never noticed any problem in the rain, and have done alot of interstate rainy driving. Doesn't seem to have any real effect that I can tell. My present coil is #12 insulated house wire, so is protected against water shorts even without the covering. I'm fixing to make me a new antenna. " My super" version. I bet it will be super ugly to boot..Most of my antennas resemble the things you see on tanks in the desert storm videos. All black except for the stinger. I finally broke down and got a new mobile rig. Went icom again due to the good luck with the 730 I had, and got a 706g. I like it quite a bit so far. MK

I haven't run my amp in a year and a half, and haven't really missed it all that much. If I'm 40 over with the amp, I'm only 30 over without. So I still make it. I took my amp apart months ago, and never put it back together as I wanted to change the caps, and replace another part. I still haven't gotten around to ordering the parts...I need to do that, as I'm afraid of what will happen to the tubes if I let them sit too long. "get gassy maybe". I need to get off my rear and get that thing cranked back up. But mainly to save the tubes rather than be an extra 10 db over 9 louder. After I do that, I'm gonna semi retire it and build a solid state amp for everyday use. I'm tired of of tube amps and their quirks. I'll keep the henry going for hard core use, but I'm gonna build a solid state "brick" to use most of the time. Only need about 500w. The henry's 1300-1400 w is overkill. I've worked qrp at times, but I get no special thrill from making people have to strain their ears. 100w about perfect usually. Maybe 500w on 75 in the summer. MK

A coupling loop is just a self-supporting length of wire connected between
the coax inner and outer conductors.

The loop need not be screened by leaving it inside the coax.

Do not connect the coax to anything else on the main loop.

For relative sizes of main and coupling loops download program MAGLOOP4 from
website below. Takes only a few seconds. Not zipped up. Run immediately.

Hi,

Any links to sites that offer specialized antenna hardware for homebrew projects would be appreciated (elements, non-conducting booms, hard-to-find element-to-boom mounts, etc). Mostly interested in UHF Yagi homebrew stuff.

I can't seem to located a source that has most of this stuff. And, I seem to be wasting too much time browsing in local hardware/electrical stores.

Thanks.

That is what the book that came with the unit said. The coarse tuning on the unit did not allow me to zero out the reading for x but the resonant frequency of 2.5775 is correct unless I am missing something. The book also said that I could take readings directly with tuned feeders but did not mention installing a 4:1 balun.

1741. one radial better than 4 radials

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-22 13:53:49 UTC
From: ignacy@num.ads.uga.edu
Message-ID: <3a6c3e4e2vtanpl$mr2ice@news.uga.edu>
Source record: 171712

I was under the impression than more radials is always better. Last week I tried an inverted L with a drooping end and 3 20m radials. The results were poor. To Europe, I was heard l;ast and just barely. I added two extra radials and tied them to a fence, but the antenna did not seem to be any better.

I put the approximated dimensions of the antenna into EZNEC. It showed that the antenna with 2-4 radials was about 6db down from one radial. Apparently, with short radials, they radiate, and subsequenly almost all the power ends up as ground loses. The losses with one radial were much lower because of low current in that radial.

I left only one radial in my antenna, and the performance increased quite a bit. I could work every station I heard. Apparently 6db is not to be ignored on 160m.

I remember a description of an antenna for 160 and 80 m in this newsgroup that could be called either a vertical folded dipole or an inverted L with one radial. The author claimed great successes DX-wise.

Any comments?

1745. Dipole-short multi band portable

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-22 15:01:21 UTC
From: Rudy Marcelletti <rudym@net-link.net>
Message-ID: <3a6c4e6c$0$35019$44a10c7e@news.net-link.net>
Source record: 171620

What is the best way to make a short, multi band dipole to cover at least 10 through 40 meters, and possibly 80 meters. I plan to feed at center with 450 window line direct to MFJ 986 line flattener. I would like to be able to rotate this so am planning to use bamboo or fiberglass fishing poles and wrap wire around them in helical fashion. The longest poles I can find are about 20 feet long but to get any kind of strength and minimal sag, I can't use the tips ror windings, but could possible just let the "tail" of the wire hang off the ends a few feet. Should I just helically wind wire on the rods evenly out to the ends and let a few feet dangle? If so, what spacing between wraps--1", 2", 3"? More? Should I wind a coil somewhere on the rods? If so, how many turns and at what point away from center? With 1" spacing, I can get about 14 feet of wire on the first section, then less further out sections due to smaller diameter. I was thinking of using maybe 4" to 6" spacing between turns on the first section, then about 1" less spacing on each section further out in hope of getting more capacitance out at the ends and maybe a bit of gain on the higher bands. Wrapping wire in this fashion I should be able to get at least 65 feet of wire or so, and am thinking of 16 or 18 gauge to save weight.
Height of this antenna will be 35' on a fiberglass mast. How do you all think this would compare with performance of an 80 meter inverted V on this mast fed with ladder line and used on the higher bands?
Should I use less wire, say 35 to 40 feet, and skip 80? Am I wasting my time?

1746. Re: MFJ-1750 2m 5/8-wave groundplane antenna?

Newsgroup: rec.radio.amateur.antenna

From: Mark Kenward <ae8844@wayne.edu>
Message-ID: <3A6C4C72.D91B9CE3@wayne.edu>
Source record: 171717

I have done the following. Got a Hustler(Newtronics) SF-1 "buckbuster'
ant mounted it with a 3/8-24 mount to an aluminum plate. Abt $10.

Taken 4 20" wires and made radials and tuned appropriately.

I have used this antenna since 1977. As a bonus, it will load on 440.
Probably not efficient, but the rig is happy and it works.

73.

Are you talking about radials on the ground or elevated?
One elevated radial adds some horizontal component and fattens the vertical's lobe. Over poor ground elevated radial can make antenna be more efficient and gives some directivity in the direction of the radial.
ON4UN has 4 square on 80 m using verticals with single radials and over extensive radial field shared with 160m vertical.

Source record: 171623

It really is meant to be used with a long wire. I tried wireing it to a dipole and also a vertical that was fed via coax.

While it would tune up and present a very low swr to my Icom-706, it wouldn't actually radiate much out of the Dipole or the Vertical whip. It isn't designed to be used to send on a transmisison line and then the antenna. It's expecting to be the base part of the antenna.

Allmost all of my 100watts of power was being lost as heat and stray rf around the AT-120 and the coax.

On the otherhand, I set it up outside and flung a random wire over some tree limbs and worked a dx on 20 meters ssb with a good report.

I would be interested in finding how to modify mine to drive a coax.

Cecil's idea is a take off on Larry Cebik's '44 foot solution', a great backup and/or portable antenna.

See details on LB's site www.cebik.com

You'll also find a wealth of additional information to help you in your quest for a portable antenna. You would do well to also search Google.com (or others) using QRP as your keyword. Many excellent QRP sites offer multiple avenues to enjoying portable amateur operations and coverage of the antenna area is a main fous with these groups.

Bests,

Patrick

I'm planning to use a longwire (about
150 to 200 ft of 12 gauge solid wire)
for 160/80/40/30 meters using a LDG
AT-11MP auto tuner with 4:1 Balan.
Question is do I have to use earth
ground on the Balan connector (marked
for ground) ?? I used a longwire about
20 years ago and don't remember grounding the tuner (Homebrew) then.
Remember getting a few good shocks, but
being told not to ground it.
Thanks for any help.

Message-ID: <3A6C81F3.820C666F@IEEE.org>
Source record: 171632

The latest "Science News" reports that Lucent engineers have
discovered that in addition to horizontal and vertical polarization,
EM waves can be polarized along the direction of travel, i.e.
another dimension added to polarization. They say:

"The addition of the third (dimension) permits the polarization
of the electric and magnetic fields to vary independently. That
means six separate polarization signals can be transmitted
simultaneously on the same frequency."

Is this Unspread Spectrum? :-) Wonder what James Clerk Maxwell
would say?

Why does it matter? You're the one drifting off frequency, Stew.

The whole basis of your proposal is that getting a ham license is too demanding for young people. That's the fundamental premise upon which your whole concept is based.

Yet I and many others have provided numerous examples of young people who have passed the tests, gotten licenses and gone on the air as responsible, skilled amateur operators. The license requirements are NOT the problem.

Hans' Dick-and-Jane story is right on the money, too. He and I have diametrically opposite views on many licensing questions (code tests, number of classes, etc.) yet we both think this "colt" thing is a nonstarter. That oughta tell you something.

There are several problems with this proposal:

1. As a 15 year old, I can tell you that the most interesting thing of ham radio is DX, not short range VHF communications.
2. This proposal would isolate the newbies, if there are not any other recent "Colt" licensees around, they would quickly grow bored and would not upgrade. Chatting with people who have been around a while and who are talking about the Walk-a-Thon or picnic the local club is involved in or the great conditions on the HF bands today.
3. The Tech license is already extremely easy to get. I got my Tech just over a year ago and it took about a week to study enough to pass the test, and that was with 55 questions on two tests, not 35.

While I agree more young people are needed in the hobby, the problem is not the license structure, which I believe to be perfect, it is the PR deficencies.

Message-ID: <94i6je$dnb22$1@ID-20128.news.dfncis.de>
Source record: 171635

I have figured out that the transmitter will not deliver full power to the load unless the input and output impedances match,and downward sloping ground radials lower the impedance of a 1/2 wave vertical antenna.So does this mean that a A99 w/o the ground radials has a higher input impedance than 50 ohms? If i had access to a noise bridge i would measure it to be safe.

What about this as a proposal. Leave everything as it is as far as licenses
are concerned. But, then eliminate the rule that you can't charge money
for testing people. And, then work to get the FCC to cut a deal
to allow, for example, Radio Shack and ham radio stores to give ham radio
license tests right in the store -- and set up a computer system to give call signs
right on the spot. Then, the stores could make a little money giving the test.
And, might pick up some extra sales from new hams.

If real money could be made from the extra sales, the stores would give the tests free.

Perhaps you can ask Radio Shack whether they think your proposal is viable.

The money they charge is for all the expenses of testing - there isn't a
mandatory charge

What about this as a proposal. Leave everything as it is as far as licenses
are concerned. But, then eliminate the rule that you can't charge money
for testing people. And, then work to get the FCC to cut a deal
to allow, for example, Radio Shack and ham radio stores to give ham radio
license tests right in the store -- and set up a computer system to give
call signs

You could even have the test on the computer, the computer than could grade your test(s) and as you pointed out issue your call sign on the spot. Then the computer could pop up what the store had in your price range. You would then press your selections and walk to the front of the store, pickup your license and equipment and head home ready to operate.

We could do the same thing from Mall kiosks to attract young people. This could be coupled with playstation rentals, beepers, and cell phones. A one stop communications and entertainment kiosk. ARRL could create a Sony playstation and gameboy cartridge to teach amateur radio, along with an amateur radio adventure that would require simulated contacts with DX countries to obtain clues to finish the game. Wow! I wish I had thought of that. The only problem is getting it by the old elitist hams that think you should learn a bunch of code and radio nonsense to gain what is rightfully yours because you want it..

I do not think there needs to be a new Amateur service, but I also think you are perhaps being a litle hard on the guys commercial and money connection etc. After all, it was Tandy Corporation that made the FRS proposal to the FCC..and Tandy is commercial for sure..(ie Rradio Shack)

I don't like this idea very much. The part that worries me is as you say, they "might pick up some extra sales from new hams". Without accusing any store or anyone of dishonesty, I think it's a bad idea for the test giver to have such an immediate and direct financial incentive to have the examinee pass.

Money makes the world go-round. Methinks. And if you want to
get more young people in the hobby, I think you need the kind
of marketing muscle that Radio Shack can provide. And, I think the fraud
issue here is over-estimated. There's been fraud
in the testing system as it is. If you had big companies involved,
who had lawyers, they could snap the whip with the employees.
And, they'd be better positioned to enforce standards, than random
individuals. I think.

Just enact some fines for cheating. Hire a few people to go
around, and masquerade as applicants to keep the system clean. And,
open an office, that would handle reports of fraud, and then
investigate as a criminal matter. It'd probably be cleaner than
the current setup.

The enabling legislation clearly says that examinations are to
be given on a "reimbursement for out-of-pocket expenses" basis
which precludes making a profit. [47 USCA s. 303(f)(1)(I)]

George,
In general your correct in what your thinking about
matching impedances. 'Droopy' radials is one way of
changing the impedance of an antenna. But that's not
the only way. The 'A99' uses a matching scheme that's
different (rings). Both do the same thing. So do
gamma matches, delta's, etc.
'Doc

I think I'd ground the tuner/balun(?). It's being
picky, but your talking about a 'random length' wire
antenna, not a 'long wire'. A 'long-wire' is one that's
longer than a wave length for the particular band.
'Doc
PS - If it doesn't work too well grounded, try removing
the ground.

I would suggest that you rethink that tact.

Did I miss out on the announcement where you had been appointed Usenet enforcer?

net protocol does not allow me to alter the headers on a thread I did not start. As I am not the author of this thread, you are addressing the wrong party.

I also note that your message was sent to all the newsgroups as well.

I built a home-brew 6m horizontal loop using 12 gage wire. The feedpoint
measured about 12 to 14 ohms so I used two quarter wave sections of RG-58 in
parallel (25 ohm) to match to a 50 ohm line. Worked great.

QRPers are like the guy on the newsgroup who asks you a question, then posts instructions to unmung his mail address because he doesn't get on the newsgroup often.

Why, because he doesn't want SPAM?

Don't get me wrong, I have no problems with QRP operators, But, I sometimes feel as others on here that the awards should go to those that work so hard to pull them out.

My other peeve is the guy in a DX pileup who signs QRP and then you find out he thinks 100 watts is QRP.

Message-ID: <94ihfm$i1f$1@uranium.btinternet.com>
Source record: 171655

Dear Max,

Don't ground the main loop. Don't connect the main loop at RF to anything.
Keep it as isolated as possible.

The coupling loop is just a self-supporting circular wire between the inner
and outer conductor of the coax feeder. It is mounted in the same plane as
the main loop.

The conductor diameter of the coupling loop need be no greater than the
inner coaxial wire diameter because it carries the same relatively small
current.

The coupling loop need not be screened by extending the coax braid all the
way round the coupling loop. Waste of good copper braid and plastic.
Disregard the old wives.

For radiating efficiency and other data, including diameter of coupling loop
relative to the main loop, download program MAGLOOP2 from website below.

Download in a few seconds. Not zipped-up. Run immediately. User friendly.
Absolutely free to USA citizens and other similarly privileged persons.

Source record: 171656

With a 1/4-wave antenna only one 1/4-wave elevated radial is needed. Any
additional radials will not improve efficiency in the slightest degree.

Whether the elevated 1/4-wave antenna is horizontal or vertical it matters
nothing - with one 1/4-wave radial it comprises a simple centre-fed
1/2-wave dipole.

Perhaps bent in the middle. So what ?

And that's the end of the matter.

Thats what i was afraid of , the tuning rings are missing on this Antron99
and i suspected something was wrong when i inspected it after puchase , SWR
is minimal -1.1:1 from 27.855 to 28.855. I would prefer a bandwidth centered
on 26.965Mhz. Now i am confused as to why the SWR is low even though i have
a severe impedance mismatch because the matching device (tuning rings) are
missing. The base of the antenna is 1&1/4meters high and i am using 75ft. of
RG8X coax with a RCI2950 for motivation....
by the way "hello doc" nice to see you over here....
I was afraid of "death by fire" if i posted Impedance mismatch on rec. cb

Sounds like another way of describing a near-field condition. There's a radial field component (the "third dimension"?), and the ratio of E and H components is not 120*pi (independently varying polarization?). Sounds like mumbo-jumbo, but I'll have to see if I can find a copy of Science News. 73,

Message-ID: <94ijbu$5dp$1@neptunium.btinternet.com>
Source record: 171573

You will find a few, 3 or 4, buried radials useful. Use your metal domestic
incoming water supply pipe as one of them. That may be all you need.

Forget all about a balun. What on Earth do you want to match to which ?
You've been reading the wrong magazines.

Download program ENDFEED from website below for estimates of radiating
efficiency, etc. The program will also compute L uH and C pF component
values for an L or T 50-ohm impedance matching network.

Download in a few seconds. Not zipped-up. Run immediately. User friendly.

If a weak signal turns out to be someone running 100 watts, do you fault him for not having a kW amplifier? But more fundamentally, if it's such a burden to copy a weak signal, why do you answer one? Or does copying a weak signal become a burden only if you find out the other station is running low power? It doesn't make much sense to me for someone to respond to a weak signal, then complain because it's weak. What am I missing here?

Reg- I usually read your input with pleasure, but this time I think you
are all wet. I'm not at all sure what all the effects are, but I'm
pretty sure the imbalance created by having one element in the relative
clear (the vertical), and the other affected by the proximity of the
soil below it, (and usually parallel to it) is significant, and I'm SURE
that's NOT the end of the matter.

Care to expound on the result of the imbalance I described? I really
would like to get more info, and a better feel for this.

Marketing muscle? Is this from the same group of drooling no-loads I've encountered in almost every RadShack I've entered over the past several decades? These folks panic when a customer refuses to provide his name and address.

The people who are Radio Shack's customers seem to be from several distinct groups: a) those who need a part in a hurry and can't wait for delivery from a "1-800" house (I generally fall into this group), b) those who don't care about price, c) those who don't care about quality and d) those who are waiting for a spouse to finish shopping at the mall.

I don't think we need individuals who are incapable of identifying an electronic component administering amateur license testing.

Whoaaa!
The above statement could be valid for dummy loads or freaktennas and CFAs.
Have you ever looked at the radiation pattern of horizontal dipole at various heights, and verticals with various slope elevated radials (single or multitude)?
Then you add various ground conductivities and you have "beginning of the matter". Vertical has nulls where horizontal has lobes and vice versa. Are you trying to tell Tom that he waisted 119 radials?

For what ever reason this cross posting continues to be a problem usually stemming from the ham groups. You surely have control to which NG you direct your response to. It figures you would follow everyone off the cliff to adhere to protocol. Do you believe that anyone who is only interested in CB gives a rats @$$ about some new Brownie license to use a radio? This NG is CB no license, no policy etc. So why even post it here?

If I have to nominate myself as the enforcer of this group so be it others will support the cause. If the amateur NG would like all of the CB posts crossed to their NG it can begin immediately. You see it is like one guy turns on an amp then another then another and pretty soon the whole band is unusable. Is it time to see who's is bigger? Or can this just end and everyone take their posts where they belong?

Since I don't know the origins and really don't care to waste time researching I am posting back to all the groups so that no one can later say what happened and why. This thread being crossed to the CB group can be stopped if you want to. Or you can get prepared to read many more posts that don't pertain to your groups.

Hey, I know this is probably the wrong place to be posting this, but I need some help. I have recently purchaced a portable wireless communication device with a standard portable radio type antenna. Now the range of this sucker is not poor, but at times I need it to be greater. Is there any way of enhancing the antenna so that the range will be increaced? I have tinkered with things like this in the past, but to little avail. Any response would be greatly appreciated. and if possible, could you e-mail the response to

ghettowah01@aol.com

Thanks

I think thats the problem. Being as the radials/radial are elevated,they need to be resonant to really work. If you have 20m or appx 60 ft radials on a 160 L I don't see how they can do much good at all. They need to be 130 ft long if they are elevated. If you run 1/4 wl radials, I bet then 4 radials will be better than 1. If you only run 1 elevated 1/4 wl radial close to the ground, it should act as half of a "dipole". Being as it does this the ground losses along that leg should be fairly high. With your half size radials elevated, I'm surprised you are doing well with any number of them. On the ground, this would be fine though.

The leg close to the ground can show quite a bit of ground losses being so close I would think. I see where Reg is coming from with his theory of this, but I don't really agree with it unless the antenna is high in the air, and then it's true. But to me, you can't totally go by the theoretical efficiency of antenna without considering height and ground losses. An inv L with the single 1/4 wl radial at 1/2 wl up will be very efficient and have low ground losses. The same antenna with the single radial at 5 feet? Good luck in the contest...But to me an inv L with a single 1/4 wl radial that is elevated is not an inv L. It's a severely perverted dipole. And if the radial is only 1/8 wl long as he says his are, it's a bent monopole with a weird length and fairly useless counterpoise wire. MK

Apologies to Ken M. I didn't have the origial message available to reply to directly so I had to use yours since it was the next available in line.

In reply to the original poster, I wish Sprint would put up a few towers at the schools in my town, that way my sprint pcs service would actually work. There's a cell tower at the high school; but it's not sprint. There's a tower at the new police/fire complex; but it's not sprint either. I'd rather pay for an Analog Cellular One service over my nonexistant Sprint one any day.

All I get ("get in the soon-to-be past tense, ordered a Voicestream package tonight, will be here wednesday") is a signal strength of nothing in my home meaning I can't make or receive calls whatsoever. I have to go clear across town just to get a signal strength of 1 or 2 bars. It's kind of ridiculous having to go clear into the next town just to make a decent call with this thing.

As for the effects of RF radiation, nobody really knows what the effects would be after long-term exposure. Other electronic items (AM/FM radio, TV, Microwave, etc.) also emit RF radiation to some degree, so cell phone and their towers shouldn't be given all the blaim.

No, you should not connect a jumper from a tuner's chassis to either of the balanced [balun] binding posts if you are planning to feed a balanced transmission line. You should ground the tuner's chassis to the station's ground in any case. I hope this helps.

1806. Re: One radial better than 4 radials

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-23 09:22:35 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3A6D4D5B.F321A5B8@eznec.com>
Source record: 171579

Modeling has shown that a vertical with one radial close to the ground (not the example Reg gives -- he specifically said that the radial was high) is pretty inefficient(*) in that a sizable fraction of the power is lost in heating the ground. You can investigate this very easily with EZNEC v. 3.0, even the free demo version. Set the Plot Type to 3 Dimensional, the Ground Type to Real/High Accuracy, and the Wire Loss to Zero. The model shouldn't contain any resistive loads. This makes the ground the only source of loss. Run a far field pattern and look at the Average Gain. The deviation of the average gain from 1 (0 dB) is the ground loss.

This ground loss includes not only the loss due to current returning via the radial(s), but also the loss occurring due to reflection from the ground some distance out from the antenna. So you should compare various radial configurations with each other but be careful about extending the results to predict what would happen if the radial system were perfect. Example file Vert1.EZ is a vertical connected to "MININEC-type" ground. This ground has no loss from returning currents (the antenna connects to the ground with no resistance); in this respect it acts like the antenna has a perfect radial system. Yet the average gain is -5.14 dB. Does this mean that only a third of the power applied to the antenna makes it into the distant far field? Yep. The rest heats up the ground as it reflects. Changing the ground type to perfect shows an average gain very close to 1 (0 dB) as it should be. With the Vert1 results as a benchmark, compare radial systems at various heights with various ground qualities -- you should find it interesting. One more caution -- remember this says nothing about how strong the field is in any particular direction or elevation angle (although EZNEC can certainly tell you this too), which is what ultimately matters. The Average Gain simply shows you what fraction will arrive at distant points.

Roy Lewallen, W7EL

(*) Antenna efficiency is usually defined to take into account only near field losses. Average Gain calculated by EZNEC includes the effect of lossy reflection of the signal from the ground, which typically occurs largely in the far field. So the resulting figure, Average Gain, isn't the antenna efficiency in the strict classical sense. It's more of a system efficiency figure, where the ground out to a few wavelengths is part of the system. But it does represent the fraction of the applied power that actually makes it to distant points. In this sort of analysis, verticals invariably show up much worse than horizontal antennas, since a much higher percentage of the power is lost when a vertically polarized wave strikes the ground than when a horizontally polarized wave does.

I'll be very surprised if any autotuner will provide a decent match to
your rig on many if not most freqs considering the wide range of feedpoint
impedances you should expect to have to deal with. I use wide-range manual
MFJ tuners which can deal with any feedpoint impedance. You'll need a
common ground per Reg Edward's comments, ground strap the radio, the tuner
and the earth ground and radials in whatever form together. To keep the
"hot stuff" off the radio insert a choke balun in the line between the
radio and the tuner. Can be just 10-12 turns of coiled coax.

1808. Double Half Wave antennas?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-23 11:54:35 UTC
From: surf_tolive@yahoo.com
Message-ID: <surf_tolive-2301010654350001@t-25-182-42.dialup.wisc.edu>
Source record: 171581

I'd like to build a compact semi directional antenna for my
apartment to work on 11 or ten meters. I have SSB radios for
both bands but no high power "modified" CB enabled ham rigs.
I'd like a bit of more gain than the quarter wave bolted to my
rain gutter on my balcony. Any thoughts about how to phase two
dipoles or Jpoles for an extra 3 db of gain would be apreicated.
I plan to have a simple movable boom that would rotate the antenna
about 180 degrees. I know from the double quarter wave CB antena's
that the spacing has to be around 9 feet. The proper phasing cable
is 75ohm coax combined somehow in to a 50 ohm load. I have seen stacked
beams that use the 75 ohm to 50 ohm phasing cable arangement. I came
up with this idea yesterday. And i'm guestmating I might get about
5 db gain over a quaterwave which would increase my signal from my
about 3 times over that quater wave. The quarter wave would work
fine when condintions where up if I had 100 watt radio which I
don't. I have heard something like 2.15 db increase in gain you get
from going to from a decent quarterwave to a decent dipole. Any body build
10 meter J poles? dipoles would work because I am three strories up
and I would just hang down antenna wire and use copper tubbing for the
the main antenna. I may put a two meter antenna on top of this.

The chalenge is get that SSB CB radio working DX with out an ileagal
amp or a a big beam that the aparment managemt wouldn't like.

The other idea was to try a 5/8 wave CB antenna that could also work
on twelve meters as a half wave.

If any body has built such semi directional antennas I
really apreicate the advise and expereince in how to get
them working?

1809. Antenna for FM Transmitter

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-23 11:55:19 UTC
From: Pim <sebastien@altern.com>
Message-ID: <980251293.883150@remus.infonie.fr>
Source record: 171582

Hi,

I've ordered a 1W FM Transmittor on the Veronica website. I've received it today and it seems to work fine.
I'd like to broadcast only on 100m around my flat (for friends who live mear me).
The antenna must be plugged on the SO-239. The kit comes with a 50Ohm PL-259 (Dummy Load). When i plug the PL-259 on the circuit and when i use 13V at 90.00MhZ, a friend of mine can hear the signal at 50 meters. But the other friend at 100m hears nothing...
So i think i have to make a little antenna... And i dont want something expensive. I think a simple Dipole Aerial would be the best

I've seen this on a website : "Both elements can be either aluminum/copper tubes or wire. The lengths of each dipole, L, is calculated from your transmitting frequency by this formula:

L = 71/F (meters), where F is operating frequency in MHz"

But how can I plug the Dipole Aerial on the SO-239 ? What sort of cables should I use, how can I do ?? And what should I buy ?

Keep in mind that it's for a LITTLE broadcasting (i don't need 3 miles , hehe :p)

Please answer me on my email if you can : sebastien@altern.org

Thank you !!

The title, "One radial better than 4 radials", makes no sense for a non-directional antenna.

More radials is better than less.

Radials near ground are connections.

4 connections have lower loss than only one connection of the same ilk.

Suppose each radial represents a connection with a loss resistance of one ohm. Suppose a total current of 4 amps is transferred between sender and ground. This is practically a constant current circuit due to relatively high Z in the source.

4 amps squared times one ohm is 16 watts lost in the connection made by one radial.

1 amp squared times one ohm is one watt lost in each of 4 radials for a total of 4 watts lost in the connection made through 4 radials.

Best regards, Richard Harrison, KB5WZI

I appreciate many responses to my problem. Perhaps some of the suggestions went too far. I am not trying to make not the optimum 160m antenna but to set up something that would fit on my city lot, could be set in an hour or two, and could be more efficient than a shortened dipole. The main purpose of the post aside from originating a discussion was:

- contradict a blanket statement that more radials for ANY antenna with a vertical component is better.

- give praise to EZNEC

There was one question why to have a 20m radial (leg) 6 ft off the ground? The answer is feeding. One can feed at apex of an L, but with that apex 70 ft up, it is a lot of cable and tuning is difficult. With a radial (or one leg of a dipole) at 6ft, one can use a simple L network at a few feet, adding ferrites to suppress the common currents. My L network is housed in a food plastic box.

More radials for any non-directional grounded vertical antenna IS better.

As the number of radials grows, the benefit of an added radial decreases.

There is a technical letter on this in Nature, 18 Jan 2001,
together with a less technical discussion. The idea is to
use the multipath scattering between the transmitter and
receiver rather than treat it as a problem. Because the
scattered signal comes in at an angle to the direct signal
it creates an electric field which is *along* the direct
path but still perpendicular to its own direction of travel.

They consider UHF propagation in urban areas, for
example cell-phones, so that you can get large scattering
angles from buildings.

I imagine James Clerk Maxwell would have been very impressed.

rdalton1 wrote:
"I am looking for construction plans for 6mtr halo (150 watts capacity)"

A halo is a dipole, simple or folded variety, rolled into a circle, usually with a capacitive gap between its ends.

This horizontal dipole is nearly 1/2-wavelength. Capacitance between its ends is used to increase current at the gap and get more uniform current in the dipole`s length so to get more even radiation in the horizontal plane.

An adjustable capacitor between the antenna ends permits tuning and impedance adjustment.

Vertical polarization is common for mobile operation. Whip antennas are simple and effective at 6 meters. Why use a halo?

Best regards, Richard Harrison, KB5WZI

In most mobile communications systems (i.e. cellular), the RF link is established through multipath reflections. In many cases, a Line Of Sight (LOS) path does not even exist. (There is not much of an LOS path between the US and the rest of the world for HF communications either) In these cases, if the multipath signals did not exist, the communications link could not be established. As a result of these numerous multipath reflections, the total signal arriving at the receive antenna is comprised of numerous individual signals with differing polarization sense and orientation (Polarization Distortion). I have not seen the Nature or the Science News article, but this is a well known concept. I would be surprised if this was the phenomenon that the Lucent engineers were describing.

I managed to bite my tongue on that one. A "longwire" is a very specific type
of antenna which is usually quite directional. The last type of antenna a ham
needs when just surfing the bands.

Just to add a little bit more to this thread.

I agree that ,if someone responds to a weak signal, it doesn't make sense to complain because it's weak. When I CQ, I always stick a couple of "QRP"s in there. Any station answering knows in advance that I'm running low power. If they don't want to talk to me because my signal is weak or I'm running low power, that's ok. There is always someone else to talk to.

As far as who is doing all the work, most QRP rigs have pretty poor receivers (at least mine do). It very often happens that the other station hears me a lot better than I hear him. He is usually running a nice Yeasu or Kenwood with a nice receiver with good filters. Me, I'm running a direct conversion receiver with 1 rf stage and an audio filter. I can hear stations on both sides of center frequency which double the QRM. Try the 40 Meter novice band at night, with a rig like that some time.

I just think that running QRP is fun from both sides. I switch back to QRO, once in a while, and am impressed at how easy contacts are to make at the 100 watt level. I can get a 599 anywhere in the US. But with QRP, it's a little harder to get those good signal reports. I makes you pay a little bit more attention to your antenna. A little better match means less power lost in reflections and more to the antenna.

Well, just my $0.02.

> 73,
> Ignacy, NO9E

I'm confused....An inv L is normally fed at the base. Also there are
different lengths inv L's. I'll assume yours is 1/4 wl long. Why did you
want to feed at the apex? With a normal 1/4 wl inv L fed at the base,
you should need no matching network. I know I don't. "I have a 160m inv
L at this time. Only when using a longer than 1/4 wl version do you need
matching, and in that case, you usually only need a simple cap. Some
like 3/8 wl L's. etc.
In your present config, it's not's not a real inverted L, but a form of
dipole. I'm curious.. Have you tried feeding from the base of the 1/4
wave? If you are going to use short radials with an inv L , they really
must be ground mounted to do any good. That way they will be detuned by
the earth, and the length won't matter. Also if you ground mount, and
use a radial system "any length", you likely won't have rf problems. I
know I don't. And I don't have that many radials at all. MK

>
> Steve, VE9SRB

Steve,

I am not a radio engineer so my summary may be oversimplified.

I agree that a line of sight path need not exist and in
fact did not exist in the experimental setup they used.

The point is that the multipath signals will come in from a
wide range of angles so that the polarization can have 6
independent directions rather than the two we are used to
thinking about (H and V). This is presumably what you
call 'polarisation distortion'.

As I understood it one can unscramble the
multipath signals by signal processing of pilot tones
added to the signal channels and actually *use*
this polarization distortion to recover the

independent channels.

Does this make sense?

Perhaps someone else has read the articles and can
explain it better.

Brian

Reid,
The simplest would be to just set another 1/4 wave antenna,
about 5% longer than the one you have now, behind the present
antenna. The second antenna would act as a reflector. Move it
to change directions.
Your over-all best bet is probably to use a 5/8 wave antenna,
practical directional antennas get sort of 'large' for in-door use.

That's what I was gonna say. double-halfwave antennas on 10 or 11 are close to 30 ft long. Not so bad if you live way up and dangle them off the balcony, but the neighbors undernetah you might not understand or appreciate it.

>3/8 wl L's. etc.

The antenna used 70 ft trees for support. Because of many trees and branches, there was limited flexibility in getting any particular length of the upper section. The wire was installed with a help of a slingshot over two trees, about 150 ft total length. Three 70 ft radials were leftover from an 80m vertical. There was no space for 140 ft radials. Because the wires could not easily be pruned and feeding was at the base, the L network was an obvious choice to get matching.

Reid, N9SYW wrote:
"The challenge is to get that SSB CB radio working DX---".

A half-wave vertical dipole is possible from your 3rd floor location with ease. Use a full-length 1/4-wave whip for the upper part. Suspend a wire the same length as your whip from its drivepoint as the lower part of your dipole.

For a little gain, add a second dipole about 17 or 18 feet from the first. You will then have a broadside array if you feed them in-phase.

Use equal lengths of 75-ohm coax from each dipole to a tee. use any length of 50-ohm coax between the tee and your radio.

Best regards, Richard Harrison, KB5WZI

You only need to place one element of the dipole ant in the center of
the pl259. This will make a 1/4 wave antenna. I used to use one on my
2meter xcvr and it worked great. Just solder the center lead and put a
90 degree bend in the wire.
What your range will be is knot known but should be sufficent for your
purposes.

Not connected with aerials but is to do with grounding:

I've just got my txer and other things for my station. I read that the tx and atu need grounding. Is it alright to use the water pipes (assuming they're metal all the way to ground)?

The manual does say "don't use gas pipes (sparks?) or electric conduit"

Oh, and what should be the maximum lenght of the earth wire, or doesn't it matter?

Thanks,

Yet you continued to post to the "no-code kills" thread long after you promised to stop. At least 40 posts on that thread, involving all sorts of things like your experiences in aircraft in South America, were posted to rraa. Many were posted ONLY to rraa. Only about a third of them involved me in any way.

> Jim, N2EY, is redirecting everything back to r.r.a.antenna where it
> doesn't belong. That's the reason for the disconnect.

You keep redirecting it because you know I don't post to policy anymore. I made this exception to avoid any more of that.

> Jim will not
> admit that there ever has been a single code-tested ham using Morse
> equipment for the purpose of jamming.

That is simply not true. I just won't play your games. So you are distorting and making stuff up about me behind my back.

> He refuses to condemn code-
> tested hams who use Morse equipment for the purpose of jamming since

> he says there never has been any.

Wrong, wrong, wrong, Cecil. I have repeatedly condemned ALL jammers on the ham bands, regardless of testing or mode. The ones you mention are a subset, and so are logically included.

> That's because any admission of
> such would violate the immaculate conception virginal religious
> aspect of Morse code to the PCTA.

Nonsense. I just won't play your games anymore.

Much of what you have written about me is simply not true, Cecil. I have pointed out your mistakes above. You will not admit them, of course.

Anyone who believes what Cecil has written can check deja.com and read my posts for themselves.

Enough of your games, Cecil. I'm sorry you are so bored that you have to spend time trying to "get other people's goats".

Game over.

Back in Dallas, in the late Fifties, all the 6-meter guys had
halo-looking antennas on their cars -- dunno who made the things, or
whether anyone still makes 'em half a century later, but they were
sure common in those days -- course, back then, repeaters were unknown
and everyone was working simplex and everything was pretty much
horizontally polarized -- might be different now.

I have to agree, QRP is fun. A few days ago a ham friend was in the shack and we came across a BY calling CQ. Just for fun, I cranked the power down to five watts and called him. He came back on the first call and it was quite a kick.

On the other hand, I firmly believe that Life Is Too Short For QRP and will probably never do that again. :-) More power to those who wish to run QRP (oxymoron intended).

For the purpose of preventing electrical shock, a grounded AC outlet is all that is necessary. Just be sure there is continuity all the way from the cabinet of your rig and atu to the round plug on the AC cord.

For purposes of transmitting, the only ground, if any, should be at the antenna, not at the rig. Trying to create an antenna ground in the shack will usually cause the shack to be full of RF when you transmit (surprise!).

If you have a specific question, please ask.

No, no, Bill, it is "less power to you!" :-)

Seriously, you probably WILL do it again. Maybe you will try to do it with 100 milliwatts, just to see if it gets through. :-)

Sounds like you are a DXer, so I have a suggestion that may bring the fun back to the thrill of the hunt. While you are waiting for the volcano to erupt somewhere and create a new country, the next time you hear one that you have already confirmed by band/mode, crank your drive control down to 5 W and work a new one. Suddently, working another G station will be fun again! See how long it takes to work a hundred, then a couple of hundred. See if you can develop that knack for cracking pileups with 5 W; I have cracked 'em with 250 milliwatts, and you aren't going to be outdone by a QRPer with an invee up 40 feet on 40 M, are you?

Okay, here's the ULTIMATE challenge -- beat my all-time world records for points-per-watt in the ARRL CW SS -- 56 QSOs in 31 sections, if memory serves, at 10 milliwatts, for a PPW of 347,200. :-)

Ok, I just remembered - I did do it again. A couple of nights ago I was working a fellow in Dallas using MFSK at about 100 watts. He suggested I try lowering the power in stages to see what would happen. To make a long story short, at 500 mw my signal was still almost 100% copy. Only when I went to 100 mw did copy cease. And it WAS fun, for sure.

Maybe I will take up your challenge to try some DXing with QRP, only I think I'll go lower than five watts just to make it hard.

Thanks for the post, Ed.

1845. 5/8 or 1/2 wave vertical suggestions

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-25 09:31:59 UTC
From: Dez <dez@cytanet.com.cy>
Message-ID: <94osih$l31$1@aristotelis.cytanet.com.cy>
Source record: 171527

Hi,

I have a 33 feet vertical which I'm currently using as a 1/4 wave
on 7 MHz. It's based fed with several buried radials of various lengths.

I'd like to try the vertical on 14 MHz as a 1/2 wave, or 18 MHz as
a 5/8 wave, but have no idea about how I can achieve a good 50 ohm match.

Can anyone offer any suggestions about matching either a 1/2 wave or 5/8
wave.

Am I right in thinking I need an LC network at the base of the vertical
(feed point)?

Any ideas?

The 75 Mhz frequencies are for R/C as you said. I don't
consider that 'normal' 'ham' use. You can't communicate on
those frequencies, can you... No '4 meter' amateur band in
the US. In the UK, yes. Here, no.

1850. Vert Pol Yagi Coax Routing

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-26 01:15:24 UTC
From: Donald Campbell <castles@jps.net>
Message-ID: <3A70CFB7.21DAFCB2@jps.net>
Source record: 171522

I just received the fiberglass mast section that I will use to mount my two meter 14 element vertically polarized yagi above my tri-bander. What is the best way to run the coax from the driven element. In the past I have run it along the boom and down the mast. Should I loop it out from the driven element perpendicular to the driven element down to the metallic mast? This would seem to be the best geometry for minimizing the coax's effect on the yagi's performance.

Trying to do this right the first time.

Thanks, Don W6QEY

1851. Re: Vert Pol Yagi Coax Routing

Newsgroup: rec.radio.amateur.antenna

Source record: 171524

The best way would be to run it out the back of the beam, then out about 1/4 wave more then down for several feet and back to the mast. Very difficult to do in most cases. Might not be too hard to do if you stacked 2 beams side by side. You could come off the back and then horizontal to the center and back to the mast.

C'Mon Cecil,

What "Mode" might that be? Which band is it practiced on? What era
are you speaking of? Is this from one of our Voyager spacecraft? Or
possible Sputnik?

Most deep space craft that I am aware of use Spread Spectrum. If that
is your choice, that millstone around your neck must be chafing by now
- don't take up synchronized swimming! There is more than one reason
why wags describe Spread Spectrum being successful... straight up.
Perhaps when they surplus some unused deep space probes; then we won't
need to pony up $100 billion to build a rig.

Is there anyone in this group, other than me, that has actually worked
on building Spread Spectrum systems? I will let you know right now I
used an ARRL publication (of the same name) that provided considerable
insight back when any discussion was as sparse as trees on the moon.

Few know the genesis of SS and its antecedents being designed using
player piano rolls to encode the frequency sequencers. Tell me about
"modern" techniques and superior digital systems. That same argument
could've worked in the 50's, trotting it out in the 21st century is
pretty lame. Why? because there is a world more than CW that is
inefficient and yet they persist as well. If this is question of
degree - then again that was answered 50 years ago to no obvious
effect except for the space program, for special applications (cost)
and for scads of bandwidth in the SHF (cost again).

Hence the argument seems to be that there are many more expensive
modes than CW as if the dollar burden is proof of efficiency.

Thanks, Evan and Doc, for your replies. I'm going to go ahead with this antenna, I have access to an almost unlimited amount of wire from a good friend. This is by far the cheapest method for me to get on the air on HF. I just upgraded to general and I'm chomping at the bit. Funds are limited at the moment, so this would work well. Thanks again.

Hi Ed,
Your right, I should have made it more clear how I work on 160. The Matchbox will not tune that band and it is in pristine shape so I don't want to modify it. I did strap the two leads of the feedline and checked resonance and it is at 1.9 Mhz with a 3:1 match. I do need to find a tuner that will match at 160. I also am using an old LK800 Amp Supply amplifier occasionally which helps a lot on the other bands. It will also load on 1.8 but I have not used it there. Are there any tuners available that will load 160 with that kind of power or would a home brew 160 only type tuner be the ticket? Thanks

Steve K9SL

Thanks, Richard. I'm looking forward to installing this antenna. I was hoping it would work, and I didn't have to run the radials all over the yard. About the only fly in the ointment is the ac service ground is at the opposite end of the house from my radio. It's less than 50', the radials will cover that much distance, should be okay.

73,
Jim

With that end fed wire, rf problems could be possible. Also you are
pretty much feeding the antenna from the shack, so the rf field will be
strong. Not to mention possible common mode problems. About the only
thing you can do is give it a try I guess and see what happens. Normally
a good radial or ground system will help decouple the antenna from the
feedline, and reduce rf problems in the shack. But being yours is fed in
the shack, that won't help you too much. And expect some bands to be
worse than others. MK

I'd use a gamma loop at the base. I think you would be able to match both bands with it. On 20m as a half wave, you would feed as a normal ringo. A single turn loop that is tapped for the best match. You also usually use a cap also. To match for 17m as a 5/8 wave, you need to resonate at 3/4 wave. So a series coil can be used as is normal, but I also think you could use the same single turn loop used for 20m on 17m. You would just tap in a different place, and not use a cap. When I had a 40m gp up, I also used it on 17m as a 5/8 GP. I used a 24 volt relay to bypass the loading coil for use on 40m. I used a normal series loading coil on that one. You can make the one turn loops out of copper tubing. The soft type used for refrigeration is the easiest to work with. One end of the loop is grounded to the base "mast", and the other end attached to the radiator. If you need a cap to get a better match, it goes from ground to radiator. The coax "hot" taps the coil for best swr. I'm guessing off the top of my head, but I'd say about a 18-20 inch loop for 20m. About 100-120 pf should be about right for a cap if needed. I make those from a length of coax. MK

Hummm, tell that to the people that have been killed right here in Houston city limits from people shooting up in the air during new years eve. Quite a few have been hit. Some killed. One was a young girl. I have a friend of mine that used to live about a mile or two away from a shooting range. One day he heard a round hit his house. Later he went outside and found a nice fat hole in the side of his chevy truck. Not a dent, a big hole. Likely a big bore rifle slug. It would have killed someone if they had been in the way. They put him in the newspaper and had a picture taken of the truck. The cops have been cracking down on the new years shooters and it seems to be slowing down a bit. Zero tolerance on that these days here. MK

If your gear uses normal plugs with the ground pin, you don't need to
worry about that. As long as the ground wire is actually hooked up, and
most all will be unless a shoddy install, that will give you a good
enough safety ground. If you are using a 12v rig, you really don't need
to worry about it, except for the power supply, and it should have a
ground pin on the plug. MK

Steve,

If you get yourself a tee type tuner and place it is series with the matchbox you'll be able to tune 160 okay... A bit more knob twisting, but real hams twist knobs :-)

For the other bands just put the tee in the by-pass position.

Hmm, I suppose if you shoot a bullet straight up, once it reaches its
peak height, it will lose all velocity, and then fall at
whatever-the-hell, Newtonian speed any object falls at, which isn't
going to be very fast, and since a bullet doesn't weight much, perhaps
it can fall on your head and there will be little consequence.

On the other hand, if a bullet is shot at a tree limb in a
semi-slanted trajectory, it may come down with some of the velocity
still behind it, and be lethel.

Did the Army really do the above test? I was in the Army Reserves, and
I don't recall us doing anything that silly :-)

Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.boatanchors,rec.radio.amateur.digital.misc,rec.radio.amateur.dx,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc

In brief, I have a multi element TV antenna with a amplifier connecting to 4 televisions. The house lot is laid out in such a way that it's very hard to string antennas up with out having them in close proximity to the TV antenna. Cable is not an option. Satellite is possible but would like to keep regular TV antenna.

At Christmas I found a Six Meter rig under the tree.(MFJ 9406 SSB/CW 10 Watts) which my wife gave me. I put up a dipole to try it out and to my surprise it works quite well. With a antenna tuner I have a 1.3:1 SWR.

My wife hasn't stopped yelling at me sense. Every time I key the mike or try out CW the TV's go blank. I have tried a HI PASS filter but that doesn't do much good at all.
My HF rigs cause no problems at all. I do have a good RF ground

WHAT AM I DOING WRONG??? HELP!!!

Any comments and suggestions would be gratefully appreciated.

Thanks

I have a GM Hazer on my Rohn 25G tower and am very pleased
with the ease of working on the antenna. I was even able to
install a WARC upgrade and a 40 meter upgrade on my TA-33
Mosley without removing the beam from the tower. (It would
have been easier with it removed but I didn't have the
manpower or room at the time)I did have a couple of problems
with supplied hardware not fitting but it was replaced by Glen
Martin with no argument so I really couldn't complain except
for the delay waiting for the "postman".

The long and short of it is, I like mine very much! It keeps
me off the tower which I am happy about at my advancing age.

Good Luck.

I was thinking of Voyager. Years ago, I read about the modulation
method and think I remember that bauds got longer as the distance
got longer.

I used P&B KUP-11D15-24 relays that I found at a surplus store for $2
each. They seemed to handle 100w just fine. My favorite RF relay is a
P&B MR11 but they haven't made those in many years.

One is likely to need one's rig during a power failure. Even though
one can run one's relays off of batteries, I didn't want to endure
the power drain. So now I use DPDT knife switches that I got at a
surplus store in Tucson. I have them mounted on a piece of plexiglas
in my hamshack window with the switches on the inside and the loops
on the outside. Two knife switches are ganged to select each loop.
It takes less time to switch the knife switches than it does to
tune an MFJ tuner and no power is required for any relays.

I have it in the back of my mind to design a bistable 4PDT RF relay
that will maintain the proper Z0 impedance and be switched by a pulse
but right now it is just pie in the sky. Anyone know of such a beast?

ground is lacking, the antenna can be damaged by the stray RF.>

Gary:
I am in the process of investigating some of these issues. Some issues
I see:
1. You might want to do some experimenting before you commit your
money. You might want to borrow HF antennas (I am borrowing Hamsticks
from my club for this reason) and compare their performance to wire
antennas you can make yourself.
2. Consider a zigzag wires if your space is limited
(http://www.io.com/~n5fc/notebk_ant.htm). I will be running some tests
to see how well they compare to straight wires.
2. You can add wire radials to provide a ground plane. Of course, a
wire antenna (assuming it isn't a dipolem or other balanced antenna)
needs radials as well.
3. Horizontal dipoles should be at a height of at least around half a
wavelength in order to radiate mainly at the low angles needed for DX.
Since few hams have this much height available for 160m, 80m, and 40m,
vertical antennas are usually used on these lower frequency bands.
You'll have to experiment to see how well dipoles can work for you.
(Perhaps a vertical zigzag dipole would work. Perhaps not.)
4. If your experiments show that a Screwdriver antenna is your best
option, you should be aware that there are cheaper ($150-$200)
Screwdriver antennas for HF (most of which have 80m, unlike the ATAS-
100). Also, there are many antennas available for 2m/70cm.

>Any ideas?

Rather than tell you to put coil A here and cap B there, let me explain what needs to happen. There are often several ways to make it happen, but let's go over the basics first.

There are two things to do when you want to match a non-resonant antenna to your feedline. First, make it resonant. Second, match the resonant resistance to your feedline. These two principles apply to everything from mobile antennas to ground planes to yagis.

The first item: When an antenna is not resonant, it means the feedpoint does not "look" like a pure resistance to the feedline. There is reactance present which has the effect of increasing the total impedance the feedline sees. You need to get rid of the reactance, and the way to do it is to put another reactance in series with the antenna, of equal value but opposite sign. This means if your antenna looks electrically like a resistor with a capacitor in series with it, put a coil in the antenna to cancel the reactance of the coil, leaving only the resistance. This is often done with HF mobile antennas. The reactance cancelling coil can be inserted either right at the feedpoint or somewhere else in the antenna, but the value of the coil will be different when it's installed at different points. The idea is to cancel the capacitive reactance so the antenna looks like a pure resistance.

The second item: If you have canceled the reactance and the resistance is 50 ohms (or whatever your feedline is) you're done. Hook up the line and get on the air. More likely, however, it will be different, sometimes GREATLY different. There are a couple of ways to change the existing resistance to what you need. One is a transformer. There are several kinds of transformers that could be used, the most common being a transmission-line transformer wound on a ferrite or powdered iron toroid core. The other method is to use a L-network or some variation of it such as a T-network (two L-networks back to back).

At this point you may be thinking "geez, I don't want to bother with all this stuff, I just want to get on the air". Ok, been there, felt that way myself.

The point is, nobody can tell you what to connect where and instantly have it work. These few paragraphs should give you enough information to get started, but you need to read a good book on antenna theory - I recommend the ARRL's Antenna Handbook. Just remember there are always two things to be done to an antenna: Make it resonant by removing the reactance, and match the resulting resistance to your transmission line. There is no magic, just basic physics. And when you get it to work... what a great feeling! Good luck, and email me if I can help with a specific question.

Do it the same way as always, won't make any
difference. Run down the boom, down the mast,
make a rotation loop around the rotor, then to
the station.

It sure wouldn`t be Morse. You will recall that the baud rate is defined as the reciprocal of the shortest element in the code, be it the on or off duration.

Any code that has an element 3 times as long as another element requires three times the baud rate of a code which contained elements of equal duration, the same as those of the longer element.

Bandwith required for transmission is proportional to the baud rate.

Morse is inefficient by design.

It seems that you might be able to understand that Morse as used in
radio isn't automatically useless as a communications mode just because
there are other more efficient methods.
I once owned a small airplane that I used strictly for recreation. I
could have used it for crosscountry travel, but chose to use more
convenient and more cost effective methods. That did nothing whatever to
reduce the transportation potential inherent in the small airplane.
So it is with radiotelegrphy. Which is obvious to all except those who
are determined to totally cast it out as a viable communications
resource.

So who is focused? YOU. You are determinedly focused on making sure that Morse communications is seen by all who know nothing of it as being, today, totally useless as a communications mode. The fact that this is contrary to its 100 year history of solid performance you feel can be ignored.
It is crucial to your mission that no one learn to use it so that your predictions will be self fulfilling, since developed personal skill is primarily crucial to its functionality. Absence of this development by next generation Morse operators means there will be no more of them.

The coils are vertical and located about eight inches apart. There are five of them with lengths, 1ft, 2ft, 4ft, 8ft, and 8ft. All except the two 8ft loops are self supporting. The 8ft loops are tied up to cup hooks under the eave of my house using Dacron cord.

It is important that the loops of ladder-line be kept apart and NOT curled up together. You could curl coax up together, but not ladder-line. I've got some photos somewhere. I'll try to find them and post them on my web page.

Anybody using broadband antenna amplifiers are just asking for
trouble. If it has a frequency response something like 47 .. 860 MHz,
then there is no wonder that it is going to saturate :-).

Are you absolutely sure you need amplification for VHF channels ?
Wouldn't it be sufficient to put a UHF only amplifier directly after
the UHF antenna and just use a passive summing network to connect the
VHF antenna into the downlead ?

If this is not possible, but Band I is not needed (channels 2 .. 6 in
the USA), put a high pass filter around 150 MHz immediately in front
of the preamplifier.

If Band I channels are required, put a 50 MHz notch filter immediately
in front of the amplifier and make sure the amplifier has a good
metallic cabinet so that your transmitted signal does not go directly
into the amplifier.

Done that many times. Connect a 3 uH coil from the coax center conductor to the antenna. Connect a 50 pF variable capacitor from the antenna to ground. Adjust cap for best SWR at 14.2 MHz. Then tap down 1 turn on coil and retune cap. Keep tapping down on coil until SWR = 1:1. Be sure to use a high enough voltage capacitor, since the antenna impedance is around 1000 ohms. No radials are necessary, although they don't hurt anything.

One common way to reinforce masting is to use another steel pipe of a
diameter that will just slide inside the mast, cut is slightly shorter
than the main mast, so that an inch or so space is left at each end and
then tackweld the inner tube to the outer mast in this small inside
space to hold it in place.

I have read just the opposite, and that a good bunch of grounded reinforcemnt rods in the concrete work fine. It may have been in the PolyPhasor text on lightning grounding, but I do not recall for sure. The text stated that the "concrete exploding" was a myth.

That's only true if both codes are capable of sending the same amount of information in the same amount of time while one uses a baud rate three times that of the other. You have to compare apples to apples. Your example does not.

Go back to the "paris" example. 50 baud Morse would require 1 second to send the word "paris" - 60 wpm. 50 baud asynchronous ASCII would require 1.08 seconds to send the word "paris" - 55.55 wpm.

For the SAME baud rate, and thus the SAME bandwidth, Morse is slightly faster than asynchronous ASCII. Where's the inefficiency?
>
>Bandwith required for transmission is proportional to the baud rate.

In the above example, the bandwidth required for a given data rate is GREATER for asynchronous ASCII than for Morse.
>
>Morse is inefficient by design.

That's simply not true. Compare apples to apples. Look at the above example and show us where the "inefficiency" is.

In evaluating a code, what is really important is how much data can be sent per unit time in a given bandwith using a given modulation. That's what should be compared, not "baud rate".

Dez, download program ENDFEED from website below. Needs only a few seconds.
Not zipped up. Run immediately.

Enter antenna height, conductor diameter, ground electrode system,
frequency.

The program will tell you component values of the L-match network, or
T-match network, or simple series-capacitor, or simple series-inductance,
for best match to 50 ohms.

You can make a good inexpensive notch filter by placing a 1/4 wave (on your 6M operating frequency) long piece of coax, shorted on the far end, across the input to the amplifier.

There is a simple device sold at many Hardware and electircal outlets for a
few buck that will check ground integrity without having to take any face
plates off. just plugs in and lets you know.

Its a UK (and a few Euro countries) allocation around 70Mhz - 70.000 to 70.500Mhz here in the UK - probably as strange to people outside the UK in the same way 220Mhz is to non-US folk.

Date: 2001-01-26 14:05:05 UTC
From: Larry Gauthier <larryg5099@chartermi.net>
Message-ID: <t7310kkddipq8a@corp.supernews.com>
Source record: 171566

I recently had a similar project on a limb over my garage, and I hired a local tree outfit to come in with a "bucket truck' and trim it. Since I told them I was not in a hurry, they arranged it when they were already in the neighborhood: backed the truck in the driveway, jumped in the bucket, cut the limb, and drove away within 15 minutes.

What is your SWR without the tuner?
All the suggestions I just read are good. Especially the Amplifier
part and the stub idea.

Try getting the swr nice and flat without a tuner.

There is NO REASON a tuner should be needed on a 1/2 wave coaxial fed
dipole. Unless your operating way off its frequency. And if you are,
that in itself will contribute to the TVI problem.

Hi Robert--

If you don't want to saw the limb only to have it drop down on your roof, why not shoot a line over it with a bow and arrow, pull up a stout rope, attach the rope to your trailer hitch, and drive away (wihtout looking back)? Then use the wire saw to prune off the remaining ragged stub.

I'm sure a trained arborist would have a coniption at the prospect of doing such a rude thing to a living tree, and the author of "The Secret Life of Plants" would urge you to wear ear protection. But, I never would have gotten my 75 meter dipole where it is without resorting to such savagery!

PS: Even though I've done this (far from power lines and other breakable objects), I readily acknowledge it's a really hair-brained idea and assume no liability for the outcome.

Bill Nelson wrote:
"I have read just the opposite, and that a good bunch of grounded reinforcement rods in concrete work fine."

They work fine to produce a low resistance ground connection. These rebar ground connections are called "Ufers", in honor of Dr. Ufer who stopped static electric detonations in wartime powder magazines by using rebars for grounding.

Ground rods have a small surface area in contact with earth. This is because they may be oh so long, but they are still very small around.

A "Ufer" is the way to get a large area in contact with the earth. This is the equivalent of numerous parallel paths, and produces a low resistance.

The fly in the ointment is that ground around a "Ufer" may not be at all homogeneous. High conductivity may be concentrated in a small area. Lightning current will concentrate in this small area. If this happens in a small volume of concrete between the rebar and earth, expect an explosion. This won`t blow an above-ground powder magazine, so no problem. If this concrete is supporting a tower, there may be a problem.

Commercial practice is to connect each leg of a grounded radio tower to a substantial ground rod outside of the tower base and to use extremely low impedance straps or cables for these connections. This bypasses the tower base to prevent lightning from splitting the tower base open.

There is a story of a drunk staggering into a NYC bar and demanding another drink. The bartender says, "Man, you`re already drunk, and what`s that stupid contraption slung around your neck?" Drunk says, "It`s an elephant whistle, to keep `em away." Bartender says, "Man, you`re crazy. Ain`t no elephants in the streets of New York City!" Drunk says, "See, it works don`t it?"

Well, ground rods protecting tower bases may be the equivalent of elephant whistles, but in the hundreds of towers in my experience, we`ve never seen a base split by lightning, and all of these were bypassed to substantial grounds. The AM broadcast towers were bypassed to the radial ground systems which are better than ground rods.

Best regards, Richard Harrison, KB5WZI

FSK is as outdated as CW. Please tell us how OOK/Morse can be sent
within the same bandwidth as PSK ASCII for the same throughput. For
instance, PSK31 has higher throughput in a lower bandwidth than does
20wpm CW.

OPEN on the far end!

Best use a piece of 'large' coax. I've used 3/4" cable TV hardline.
It's notch is wide enough that you should cut it low in freq. to keep
from killing any TV2 signal. Cut it for 49 - maybe 48 mcs --- you
can always cut long coax shorter, but you can't cut short coax longer.

Calculate the reflection coefficient (rho) as:

rho = sqrt(Pref) / sqrt(Pfwd)

then SWR = (1 + rho) / (1 - rho)

VSWR = 1 + the square root of reflected power over the forward power, all divided by
1 - the square root of reflected power over the forward power.

If you write to Bird, they will send you a graph so you won`t have to calculate.

Make that 1/2 wave and you might see a notch :-) on that frequency
(and remembering to compensate for the velocity factor) if you are
using shorted stubs.

A 1/4 wave _open_ stub could also be used, but it is harder to tune.

> than asynchronous ASCII. Where's the inefficiency?

The above sentence is incomplete. It should read:

"Using the SAME modulation method and the SAME baud rate, and thus the
SAME bandwidth, Morse is slightly faster than asynchronous ASCII.
Where's the inefficiency?"

This is clear from the context, but if viewed out of context it may be
unclear to some that the same modulation method is part of the equation.
> >
> >Bandwith required for transmission is proportional to the baud rate.

>
> In the above example, the bandwidth required for a given data rate is
GREATER
> for asynchronous ASCII than for Morse.

The above sentence should read:

"In the above example, the bandwidth required for a given data rate
using the same modulation method is GREATER for asynchronous ASCII than
for Morse."

Again, it's clear from the context but not clear if the sentence is
viewed in isolation.
> >
> >Morse is inefficient by design.

This last sentence sums it all up. It's the rebuttal to Richard's claim
of "inefficiency".

Sorry for any confusion.

Without disagreeing with either, let me simply observe that efficiency has no bearing on whether Morse should or should not be required to get a license. The spectrum we enjoy is public property. Like a national forest, it has been set aside primarily for recreation and, as such, should serve as many people as possible.

I know people who take great pride in their ability to start a fire with flint and steel. They band together both to hone their skills in case of emergency and to compete against each other. However none of them I've ever met has suggested that the government should close off portions of the public's lands to folks who cannot start fires with flint and steel. Sadly, the reverse is true of many, tho not all who enjoy Morse. These selfish SOBs want the government to deny everyone who doesn't share their enthusiasm for an antique mode of communication the use of what is, after all, public property. Justify that one for me.

I'm pretty sure they made each bit longer and integrated the signal
over a longer time period as the distance got longer and the signal
got weaker.

Who in their right mind would use OOK for ASCII? You'd better tell us
how PSK can be applied to Morse code so CW can catch up.

That is already evident and given the number of responses to my side thread, this Mode remains unidentified. Hardly matters as it is obviously not practiced by Amateur Radio (and is probably considered inefficient by design).

>You will recall that the baud rate is defined
>as the reciprocal of the shortest element in the code, be it the on or
>off duration.

That is called the bit rate. Baud is defined by symbol length which includes such considerations as bit rate. There are several symbologies, but this does not negate the general observation.

same problem

>Bandwith required for transmission is proportional to the baud rate.
>
same problem

>Morse is inefficient by design.
>
The same can be said for every technology that was designed yesterday. All Modes are inefficient to some degree and by design (this is truly a non-sequitar as designs always encompass their own failure to implement a future optimization).

>Best regards, Richard Harrison, KB5WZI

Hi Richard,

You are dead-on about the 3 times business, but defining Baud the way you do in a Mode based discussion is rather odd situation of getting the horse before the cart. The description you use would seem to derive from land based TTY where the discussion is confined to

base-band considerations. RTTY on the other hand is a Mode and as a Mode has modulation requirements that add to the bandwidth. To receive RTTY requires considerably more bandwidth to obtain a Mark than for a CW station to receive a key-down. So discussion of bandwidth in the efficiency argument shows that CW wins round 1.

As trivial as this first round is, it still contains information. The bit rates are wildly different of course, but this is still the flexibility that process's fail at where human intervention allows success.

In a perfect world CW loses all remaining rounds, true. In a perfect world no one would discuss efficiency in the first place. In this vale of tears, a less than perfect world, focusing arguments of efficiency at the level of mathematical purity to the inconsideration of the greater circuit leads to conflict. There will always be one contrived argument for either side that reveals the necessity for that Mode.

Hi OB,

Well maybe for the crafters of flint, but how about bow hunters and
gun hunters?

The Bow, an antique mode, is afterall inefficient by design. It can't
possibly compete with the modern technology of the bullet. And yet
the government allows a failed technology to dictate the season and
public lands' access for hunters. There must be some hue and cry that
I am not hearing from the gun hunters.

At least no gets hauled off to the hoosegow for practicing CW out of
band (and no one dies from a misplaced shot).

N2EY wrote:
"In evaluating a code, what is really important is how much data can be sent per unit time in a given bandwidth using a given modulation."

To compare ASCII with Morse, or Telex with Morse, requires all of the information needed to frame and transmit the data appearing as often as it ordinarily does. Many of the instruction set characters needed don`t exist in Morse code. Morse would then require special character groupings to convey the instructions represented by a single teleprinter character. Morse goes down the efficiency tubes on that basis alone. Ask yourself: Why don`t machines use Morse if it is efficient?

The usual telegraph machines (Telex) use a standard 5-level Baudot code. Normal operation is at 60, 75, and 100 words per minute. The bit rates for these speeds are: 45, 57, and 75 bits per second.

7-level and 8-level ASCII codes often run at 100 words per minute, with a pulse rate of 110 bits per second.

Telex uses 120 Hz of bandwidth to convey 100 words per minute with either FM or AM carriers.
SSB could be used to shrink this bandwidth. ASCII needs 170 Hz of bandwidth for 100 words per minute.

But you can say much more in 100 words of ASCII than in 100 words of Morse because of all the 1-character instructions available in teleprinter code.

The inherent efficiency of teleprinter codes derives from their equal length code elements and their extended instruction sets.

Best regards, Richard Harrison, KB5WZI

1918. Re: math formula for SWR?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-26 20:08:50 UTC
From: tom_bruhns@agilent.com
Message-ID: <94slga$b1o$1@nnrp1.deja.com>
Source record: 171492

Yet another way to view it: SWR = Vmax/Vmin, and that's
(|Vfwd|+|Vrefl|)/(|Vfwd|-|Vrefl|). Power is proportional to the square
of voltage, so take sqrt(power) to get a number proportional to voltage.
(There's a factor in there for the R0 of the line, but it cancels out in
the SWR ratio.) So... SWR = (sqrt(Pf)+sqrt(Pr))/(sqrt(Pf)-sqrt(Pr)).
Knowing the origins of the formulas makes it easier for me to remember
them or to re-derive things easily, rather than just trying to remember
a bunch of formulas.

Cheers,
Tom

The end feed Zepp antenna is a single band antenna. only one side of
the feed line is connected to the 1/2 wave wire element, the other wire
in the feed line is left open. The feed line is used as a tuned feeder,
600 ohm open line works best but 450 ohm ladder line will also work as
long as you operate below 100 watts on the low bands. The feeder is
connected to the 4 to 1 BALUN in the antenna tuner. You can view a file
on The classic Zepp antenna for the month of Feb-2001 at
http://n4zou.homestead.com/files/project.htm . This file changes once a
month so around the end of Febuary it will change to a diffrent antenna
design so be sure and copy it to your files for later use. It's also
printer friendly so it's black on white page and should print on only
one sheet of paper. Good luck

Hi Richard,

Again, there are more to it than that (but not much more). How many start bits, stop bits? How long are the stop bits 1or 1.5 wide? How about parity? Many of the features you describe as being necessary to bring this efficiency are missing from your discussion and skews the numbers you present above.

Problem is that with these extra "framing" bits, especially the parity bit, they are another example of "inefficient by design." Parity has been long dismissed by the software crowd as an imaginary safety net that in reality is wholly useless. The framing bits are entirely unnecessary, but persist out of habit and inertia. Computers oversample these bits by an order of 16:1, efficiency AND speed was discarded long, long ago when synchronized transmissions of ASCII were replaced by the more inefficient (but less costly) async transmission. Consider Harvard BiPhase, NRZ or NRZI, much better (faster, efficient) at moving the same ASCII codes, but as rare as hen's teeth (costs more).

Efficiency is a moving target and the example you cite is moving backwards TOWARD CW and is being used as an example as more efficient by virtue of the efficiency discarded (see the contradiction?). In other words, ASCII is an argument against ASCII (and CW too, but the same brush strokes both with the same tar).

Efficiency is not a characteristic used to arbitrate the utility of these Modes. Efficiency transcends the fine grain focus of these discussions and lies in the greater service these Modes are placed in. Will CW work for a space probe? Nuts to that, a probe's budget is already in the 7 to 10 figures, the cost of a 6 figure Mode is hardly a show stopper. Goferit! Will SS work in 160M QSO? Nuts to that, the rig is a surplus 1953 AM transmitter and I ain't spendin' any more jack on that!

What cost efficiency?

Based on personal experience, concrete can in fact "explode". There was a lightning strike, to a tree I believe, at our church about six years ago. It removed the bark from part of a tree, near the ground, and split it as well. In both directions from the tree, there was an underground phone line. The curb on each side, above the phone line, appeared to have exploded along with some of the ashphalt. Where the strike originated I'm not sure.

Dez,

For a 5/8 wave vertical, you'll need a tapped inductor. One end to the antenna, one end to ground, and the "center" to the coax. You'll have to adjust both parts of the coil. The one end toward the antenna to get resonence where you want it, the end toward ground to get the impedance down close to 50 ohms.

For a 1/2 wave, the impedance will be very high and a different matching arrangement will be needed.

Try feeding the dipole so that it has balanced RF current.
use a Balun or make a pawsee stub at the feed point
a Dipole if cut right is about 70 ohms so SWR 1:1.3 is about
OK with no tuner (the PA in the rig should handle this with out
shutting down)

In brief, I have a multi element TV antenna with a amplifier connecting to 4 televisions. The house lot is laid out in such a way that it's very hard to string antennas up with out having them in close proximity to the TV antenna. Cable is not an option. Satellite is possible but would like to keep regular TV antenna.

At Christmas I found a Six Meter rig under the tree.(MFJ 9406 SSB/CW 10 Watts) which my wife gave me. I put up a dipole to try it out and to my surprise it works quite well. With a antenna tuner I have a 1.3:1 SWR.

My wife hasn't stopped yelling at me sense. Every time I key the mike or try out CW the TV's go blank. I have tried a HI PASS filter but that doesn't do much good at all.
My HF rigs cause no problems at all. I do have a good RF ground

WHAT AM I DOING WRONG??? HELP!!!

Any comments and suggestions would be gratefully appreciated.

Thanks

Donaly:

Heh, heh... fractions of infinity...

Fun stuff...

Ever read Rudy Rucker's book on "infiinty"? Pick it up sometime and spend a Sunday afternoon pondering fractions of infinity.

Concepts like AlephNull, Dedikind Cuts, countable infinities, uncountable infinities, Cardinal numbers, sets of infinities, some of which are infinitely bigger than others, etc, mind boggling.

Rudy helps you to understand, how many points are there on the real line between zero and one. Answer is an infinity of points, exactly the same as the total number of numbers! What??? Now how many rational numbers [Numbers of the form integer/integer] are there on the real line between zero and one? Now how many irrational numbers [e.g pi or e etc...] are on the real line between zero and one.

Now what fraction is the infinite number of rational numbers on the real line between zero and one of the total infinite number of numbers between zero and one. Or are they equal, or... what???

Now back to antennas...

If there are an infinite number of "arbitrary" antennas, either invented or yet to be inventede, why then how many fractal antennas are there? And... more important...

What fraction are the fractal antennas of the totality of all arbitrary antennas? How many arbitrary antennas are "better" than fractal antennas?

Ponderosities....

Best,

-Peter K1PO

>Without disagreeing with either, let me simply observe that
>efficiency has no bearing on whether Morse should or should not
>be required to get a license.

Hello,

First off, let me say that the Morse/Baudot/ASCII discussion isn't about code tests at all. It's about the characteristics of various modes and codes, not what should or shouldn't be tested.

The whole test issue is a dead duck - a moot point - a done deal. The FCC announced well over a year ago that they were going to the absolute minimum code testing possible under the treaty, and that it was only the treaty that was keeping that much testing alive. The restructuring R&O makes this quite clear.

The FCC can't eliminate that last remnant of code testing until the treaty changes, and the treaty won't change before 2003 (the next meeting where it will be discussed). If the treaty stays, 5 wpm will stay, and if the treaty goes, FCC will drop code testing soon after.

But let's see what ya got anyway.

>The spectrum we enjoy is public
>property.

True - but it's also international public property, not just American property.

> Like a national forest, it has been set aside
>primarily for recreation and, as such, should serve as many
>people as possible.

Bad example. Neither ham radio nor the national parks, forests and wilderness areas exist solely for recreation. In fact, words like "hobby" and "recreation" do not appear in Part 97. The national park and forest systems serve a number of diverse purposes such as wilderness and wildlife preservation, research. education, resource recovery and many other things, not just recreation.

>I know people who take great pride in their ability to start a
>fire with flint and steel. They band together both to hone their
>skills in case of emergency and to compete against each other.
>However none of them I've ever met has suggested that the

>government should close off portions of the public's lands to
>folks who cannot start fires with flint and steel.

Another bad example. The flint-and-steel folks' activities do not affect, nor are they affected by, those who use matches. The same cannot be said of ham radio - every station on the air uses some spectrum and makes it unusable for others.

A better example is the way the various parts of the national parks and forests are set up for various activities. Some areas are easily accessible by road, others require an off-road vehicle, and many can only be reached on foot.

>Sadly, the
>reverse is true of many, tho not all who enjoy Morse. These
>selfish SOBs want the government to deny everyone who doesn't
>share their enthusiasm for an antique mode of communication the
>use of what is, after all, public property.

That's simply not true. All that is required is to pass a skills test. One is not required to use any mode after that.

> Justify that one for
>me.

How is it any different from the government's refusal to allow citizens to use motor vehicles in all areas of the national parks? By making some parts off limits to all but backpackers, the access of those who don't like to hike is restricted or eliminated from that public property.

In addition, consider the WRITTEN test. All hams must pass them, even if they have no interest in radio theory. They must pass tests on all sorts of stuff that they may have no interest in and may never use. Justify that one for me.

Richard Clark wrote:
"Again there are more to it than that (but not much more)."

Yes, about 30 years ago I went through the whole exercise in designing a SCADA system. After examining all the codes we could think of (including Morse and ASCII) we used a binary code with BCH check bits attached. The word length was picked to be just long enough to contain the data we needed from the commonest points in the system. If we needed more from a site we made additional interrogations. Overall efficiency was very good, data was error free, and we had no miscues in control operations.

We had hundreds of remotes which might take 3 or 4 seconds each to poll for data. Many were reached by VHF radio, any of which had to key up and settle during its cycle. So running at 30 baud was fast enough. We could go through the whole roster in 10 or 15 minutes. We could do a demand scan of any point and issue a control order at any time. Bell discontinued its 30-baud tarrif not long after we started leasing thousands of miles of their lines. Our lawsuit failed. So we built our own microwave system to replace the Bell System service. That worked very well too.

Our lawsuit failed because the FCC sided with AT&T in declaring 30-baud telegraph circuits obsolete.

Evan, K9SQG wrote:
"It (a lightning strike) removed the bark from part of a tree, near the ground, and split it as well."

Yes, it happens. Several years ago, I saw a blinding flash from where I am now sitting. It was instantly followed by a thunderous crashing sound. I stepped out to see what had happened. There was a tall steaming pine tree a couple of hundred yards away and it was a sight to see. The bolt had split the tree nearly from top to bottom and stripped it of much bark.

The same mechanism is involved, I believe, in blasting open trees and concrete. The contained moisture instantly creates irresistable steam pressure and does the damage.

I`ve also seen various chunks of concrete knocked loose from various structures by lightning. Good, well grounded, lightning rod systems can stop this damage. There must be a good ground system to harmlessly collect and distribute the excess energy and thus bypass the protected structure.

A radio tower may make a pretty good lightning rod. Ours were usually equipped with a lightning rod at the top to protect the flashing light beacon. It may also have diverted the strike away from an antenna at the tower top.

: Well, ground rods protecting tower bases may be the equivalent of
: elephant whistles, but in the hundreds of towers in my experience, we`ve
: never seen a base split by lightning, and all of these were bypassed to
: substantial grounds. The AM broadcast towers were bypassed to the radial
: ground systems which are better than ground rods.

In my many years of experience with towers, both with and without tower ground rods outside the concrete - I have never seen a problem from a lighting strike. The Ufer ground without the external rods seems to work fine.

On the other hand, I also believe in playing it safe, and use ground rods driven into the ground just outside the concrete base that are bonded to the tower legs. They may not help - but they certainly will not do any harm. And the extra insurance is very cheap.

It was the 30-baud tariff the FCC and AT&T agreed to eliminate. Both said 30-baud telegraph was obsolete. Although my company was leasing thousands of miles of telegraph circuits, we were minor users as compared with U.S. Government agencies. Some agencies discussed with us a possibility of joining us in our suit against AT&T, but in the end they opted out, leaving us alone. AT&T, to raise the pressure, more than doubled the rate we were being charged. We filed a complaint with the FCC. The FCC said AT&T could continue to collect the increased lease price but must deposit the increase in escrow for refund in case we prevailed in our FCC appeal. Checking the record, we found the FCC had made this escrow ruling many times, and not once in its long history had a coplainant ever got any of the escrow money back. Really, we began to see the hand writing on the wall.

Hi

Cutting a stub to the correct length is like playing Russian roulette.
The alternative is to cut the stub shorter than the calculated length
either quarter or half wave and use a small trimmer capacitor. Use one on
the input to the Amp and one on the out put as well. My experience
suggest that most on the damage occurs in the TV set mixer.
you can locate a stub if necessary at the TV set as well. I have had a
good results with co ax and trimmer it is very easy tune. After a while
you can simply guess the length of coax and tune the trimmer.

Thread:

Hey, I read the ComDesign article on 3D antennas, and... talk about obfuscation... that write up is almost as "tricky" as some of the machinactions of our "resident expert" on fractal electromagnetics.

It seems to me, after reading the ComDesign write up that what the Lucent folks are talking about is just "plain old beamforming" using signal processing behind a spatial diversity of antennas.

What is it that one of Shakespeare's characters said, " a rose by any other name...".

The only other possible interpertation might be the use of "circular polarization" in some manner, but their write up in ComDesign doesn't seem to be aligned with that concept.

Of course the article was written by a ComDesign "stringer" and not by the Lucent Bell Labs researchers, and so... as most "stringers" and reporters have a tendency to do, there might be some attempt at sensationalizations. And so I am hesitant to blame the Bell Labs researchers who are probably just a bunch of "straight" engineers and scientists. But on the other hand...

I wonder... is this a feeble attempt on the part of Lucent to shore up it's sinking stock price with hype and hyperbole by using a new name for something old, or...

What???

If you have followed the recent horror story of the nearly complete disintegration of Lucent's [NYSE: LU] stock market valuatio, loss of their CEO Richard McGinn in December, and loss of $$BB of sales to major competitors, I'd say it's about time they developed some "hype" to restore the LU employee's stock option positions, heh, heh.

Run a graph of the LU stock price over the last year and see for yourself.

I can just see the harried Lucent board or the new CEO saying to the "Bell Labs Innovations" guys, "why can't you announce something new?" And sending a ComDesign "stringer" down to the labs to interview them. And... presto... 3D antennas!

Anyone detect a "blip" on the LU stock price after the article? Any inside selling?

What???

A little "plain" talk about the 3D technology would be better than the
obfuscation in that ComDesign article.

I am considering buying a Screwdriver antenna for HF at my ground floor apartment.

Would it be possible to install a Screwdriver antenna at a slant if the 8 feet of clearance on the small patio outside isn't quite enough? Are there antenna mounts available that allow this? Would I be able to modify or build a mount to allow this? Can a Screwdriver antenna handle such a setup?

OK... but first a comment. Most of the arguments in this thread about occupied bandwidth seem to be overlooking the very significant effect the keying waveform has on this. Much of the bandwidth conservation that the later modes such as PSK31 achieve is due to their use of a keying waveform that is precisely matched to the overall system transfer function (frequency AND amplitude AND phase response). In general, this results in what the old-timers would call "soft keying". With machine codes (ASCII, Baudot, Sitor, etc.), recovering the binary signal is easy with voltage level discriminators. And it would be with Morse as well, but it would require interposing a subsystem between the RF detector output and the operator. Otherwise, the keying would be too "soft" to allow the required mental decoding to take place at the necessary speed.

And now you can see how implementing an optimum Morse system would go. The binary keying waveform would have to be precisely machine-generated since any timing errors would lead to inter-symbol interference when passed through the system transfer function. So the OM would have to use a keyboard. The baseband keying waveform would be derived by passing the binary output through the transmit matched filter (typically Gaussian) and then would be applied to the phase and/or amplitude modulator. If amplitude modulation (amplitude-shift keying) is used, the modulator and all succeeding stages, including the final RF amplifier, would have to be linear. At the receive end, for optimum results, the receive matched filter should be in the IF strip. The receive detector would precisely translate the phase or amplitude variations back to a linear baseband signal. This baseband signal would be applied to the level discriminator which would "decide" the binary signal states. The binary signal would then be applied to the keying input of a code-practice oscillator to provide the on-off tone desired for copying by ear.

See, we CAN have Morse well into the 21st century!

Dave, the 6 meter band's fundemental frequencies fall close to the
video portion of the television
signal. Plus, you're probably experiencing what is known as fundemental
overload. Your tv's are
acting like a receiver for your nearby 6 meter transmission. The tv's
don't have the proper
filtering to filter it outand reject that signal. The FCC sees Amateur
to non-amateur interference as not necessarily the fault of the
amateur. Usually, it's the fault of the manufacturer of the consumer
electronic device for not puttting in the proper filters and shields.
If there are no supurious emissions
from your station, then fundemental overload is the culprit. The ARRL

RFI book may give you some ideas on fixing the problem.
Did you try choke filters ont he tv(s)? That amplifier may be letting
in extra signals, too.
Good luck.

1957. HELP please - Mess of a Dipole setup

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-27 18:30:11 UTC
From: "Dennis P. Stahr" <irfutures@earthlink.net>
Message-ID: <TsEc6.209$2t5.16192@newsread2.prod.itd.earthlink.net>
Source record: 171430

Can someone explain what's happening?

I am in an antenna restricted area (what's new), and have created a "fan" dipole like as shown in the link below... near the bottom of the page under "Multiband Dipoles",

http://www.arc.itb.ac.id/rf/arrlhbk/ch20/PracticalDipoleAntenna.htm

I cut and tuned dipoles for 10, 12, 15, 17, and 20 meters with number 14 copper wire. I then connected them all together at the feedpoint. (I was told by two "old timers" that this would be OK).

I feed it with RG-213 (70') and the center of the dipole is about 6' above the center of the roof. The ends of each dipole are then splayed out and tied down at various points along the roof.

Big mistake I guess, but the dipole is not externally grounded, only gets its ground through connection to the rig which is very well grounded with #6 copper wire to dual 6' grounding rods.

My TS-870s internal tuner will match each band (and very quickly... within about 2 seconds), but just for fun I tried an SWR meter on the back of the rig and found I have HORRIBLE SWR. It does not find low SWR anywhere on any of the bands.

Is the TS-870 actually finding the resonant dipole for the band or is the tuner just doing me a favor, and I am radiating 100 watts out but am QRP off the antenna with a few watts?

Thanks in advance for your serious help and even for your comments about me being a complete idiot.

Dennis - KF2XL

Hi Lamar,

Ah! So long as gun hunters are not required to demonstrate profiency
with a bow; then they have no grief with the government's exclusion of
them from the field of hunt to favor their bowed friends.

Sounds equitable.

The internal antenna tuner is just matcning to whatever SWR on the line is. It does not 'know' what antenna is being used. You did not state what the swr is or if you tried looking up and down the band to see where the swr dropped the lowest. Antenna charts and formulars are only a good starting point for antennas near the ground. You normally install the antenna and check the swr at several points in the band and then adjust the length for the lowest swr at the frequency you most use or want. The lowest might be around 2 to 1 for an antenna near the ground.

A dipole antenna does not need a ground to work as far as the RF is concerned. There are many reasons to use a gound with a dipole, helps with TVI, safety incase of a short circuit, an so on.

The dipole with the lowest impedance will accept the highest amount of
power. With any luck, that is the dipole nearest resonance.

You could choose one band and see if shortening (or lengthening) that
particular dipole will reduce your SWR. Almost no home-brewed antenna
works as designed without some fine-tuning.

Dennis,
You forgot one step, after connecting all the
seperate dipoles, you have to re-tune each dipole.
Each will affect the others, so you have to go
through that 'tuning' several times, probably.
The tuner in the radio will/should handle the
SWR with no problem, as you said. Without using
the internal tuner, your SWR would probably be all
over the place, just as the external meter shows,
thats normal if you haven't tuned all the dipoles
together.
Sounds like things are normal...

Most sincere thanks to you great people for all your help.

Concensus appears to be individual retuning. I can handle that. Will have to wait until the neighbors are working to "sneak" back to the roof. They can see it there, but would really draw attention if I was up there with them outside.

I'm just happy that it sounds like I may, at least, be on the right track, and that the initial concept is correct. By the way, the SWR with the meter was over 5:1, and, that was across the entire band, for each band. On 10m and 20m I got a small dip near the low ends, so maybe shortening is the way to go. I will try to get up there during work days next week.

I have seen the very professional posts of each of you guys before and I sure do appreciate the kind and quick responses.

Thanks again,
Dennis - KF2XL

There are 2 considerations, first resonance and then matching. Use a griddip meter at the antenna and adjust the length of the elements for resonance at your desired freq. Then it is time to use the swr bridge to adjust the matching by sliding your wires up and down.

A J-pole is nothing more than a 1/4 wave matching section feeding the radiating element. Which side are you adjusting for length? What side are you connecting the center of the coax to?

You should adjust the long side and connect the center of the coax to the long side.

Hi Dennis,

Since you are feeding a balanced system [dipole] with an unbalanced feedline [coax] it is possible that the feedline has become an active component of the antenna. Before you go through the tedious task of tuning each dipole, I suggest decoupling the feedline by installing a 1:1 balun at the antenna feedpoint. Another possibility is that the antenna may be reacting with the house wiring under the roof. In this case, a repositioning or reorientation of the antenna may be required.

It's hard to imagine that every dipole in the array, even with each being slightly detuned by the proximity of the others, will produce a VSWR of 5:1 or greater - unless your length calculations were_way_off mark... hi

Yup - plus another factor: security. The original reasons for SS were resistance to jamming and interception.
>
>Hence the argument seems to be that there are many more expensive
>modes than CW as if the dollar burden is proof of efficiency.
>
Exactly.

There is one thing about SS that is rarely if ever mentioned: antenna bandwidth. At UHF and above, it's not much of a concern. But at lower VHF and HF, it is a big problem for hams because most of us cannot put up log-periodics other broadband-yet-efficient antennas. The HF hams who would benefit the most from SS processing gain are those who can't put up decent HF antennas.

Resistive-loaded designs like the T2FD are one possibility - but they are neither small nor efficient.

Hi Dennis
I have an antenna like this.Mine is 80 meters thru 10 meters.Four diploes to one feed point, and I do use a 1:1 balun at the feed point.The elements are only spaced apart a few inches.It was a little tricky tuning because one element affects the other.Most of them came out to be a little longer than standard diploe length.Start with the lowest band(longest element), then go to the next lowest band, when tuning.Once you get it tuned it should work great! Automatic band switching, just tune to the band you want to operate on, and go.
Good Luck!

I made 5-6 equal TVI filters with two sets of tuned quarterwave lines
using up to 1cm pvc coated wires to adjust the end capacitance.
Notchdepth is 85dB on 144MHz, but they covered most of band III with
minimum attenuation. So I see no reason for this shouldn't work on 6m,
airspaced trimmers may be a good choice, but your suggestion using
needles to short is usually overlooked by amateurs

The note is published in Radcom April 1982 pp320, Technical topics,
"Double stub 144MHz TVI-notchfilter" - it is also found in Technical
topics scrapbook. see

Hello Dennis I am sorry to hear of your problem but I will not go into the
neighbor issue,
I will try to help you get to enjoy your radio and as you get acquainted with
your radio hopefully
your neighbor problem will resolve itself.

First off paralleling dipoles more than maybe 2 bands where you can orientate the
dipoles at 90 degree angles or close to it is doing nothing except asking for problems.
The dipoles will detune each other and unless you want to adjust each element per each band and frequency and then go back and forth and walk them all in.
Then if you manage to walk everything in to the portion of the bands you want expect narrow bandwidth due to the interaction of the other elements.
Just forget the multiple dipole issue and throw the whole thing in the garbage!

The problem is to get the power to the antenna so it will be able to radiate and neither low SWR or resonance is needed or sometimes even desirable.

A J Operator of 35 ohms with a Z of 50 ohms will cause a 2 to 1 swr and the loss of the feedline
is increased by the square root of the SWR, therefore if the swr is 10 to 1 the extra loss will be
3.16 times that of a 1 to 1 swr.

70 feet of RG-213 at 14 mhz should have a loss of .55 db, the 10 to 1 swr will increase the
loss to 2.18 db. If the antenna itself has the 10 to 1 swr the radio will see a swr of about 6.2
and the 2.18 db loss will amount to about 40% leaving a shade over 60 watts to the antenna.
The loss will of course increase with frequency.

You under normal conditions would not ground your dipole as it is balanced and independent
from ground, neither do you need or want a balun at the antenna.

Now the way around your problem your 70 feet of RG-213 will lose .44 db perfectly matched
and a 70 foot length of 450 ohm ladder or similar under a swr of 15 to 1 under the conditions you
could expect from your installation, low driving Z maybe 30 ohms and a J Operator of 100 or more
ohms giving a swr of 15 to 1 has lower loss then your RG-213 when perfectly matched.

What you may want to do is get some ladder line, 16 gauge stranded is fine run what you can
as much in the clear as you can try to have both sides balanced to avoid RFI and TVI
run that to a balun either 1 to 1 or 4 to 1 homemade or store brought you may want to try to
pick up a old center balun and hook the feedline to the output and the coax to the output
and even with the extra loss of the balun the system will have less loss than anything you will as a
practical nature be able to use. Just make sure the that the antenna is more than a quarter
wave and hopefully closer to a half wave at the lowest frequency you wish to

transmit on and let it fly. 16 gauge insulated wire is fine as a matter of course I would use
insulated wire to keep it from arcing to something dry and try to use a flat top as
using a inverted Vee on harmonics will raise the radiation pattern to the point you
might talk to passing airplanes but little else.

Just because you are using a cable of a specific impedance doesn't mean that is the
impedance at the input of the line and unless you have a swr of 1 to 1 or next to
it I guarantee you will not have the same impedance down the line unless it is a

electrical 1/2 wave a technique used to match antennas. If your house and lot is such that
you can get a 30 foot flat top, the antenna will work 14 to 30 mhz and be of some use
on 10 mhz.

You may want to have 1 or 2 sections of ladder line of 5 to 10 feet with alligator clips on all
conductors should you have a problem loading on a perticular band or subband.
This extra length should shift the input impedance to where your radio will be able to
find a match should the tuner start hunting.

Without folding your antenna back on itself 50 to 60 feet will be great from 7 mhz up.

Your radio was not finding the resonate point resonance is J=0 and there is nothing
magic or holy about it, as far as SWR my meter took a walk years ago and I might

have a total of 5 feet of coax used as interconnects and that's it.
If you have a question feel free to ask

Do you actually have a valid Amateur license and if so what class do
you have,
What happened to the tests?

A half wave dipole is 468/F 120 feet for 3.9 MHZ and 130 feet for
3.6 MHZ

A half wave at 7.15 MHZ is 65 feet 6 inches . Cut the wire in the
middle and
connect each side to opposite sides of a insulator. Skin your cable
and connect
1 of the 2 feedline conductors to each of the elements.

Depending on where you want to operate at parallel the dipoles and you
can run
one as a inverted Vee and the other as a flat top or if they are in
the same plane
try to maintain a 90 degree spacing between the dipoles.
I do not like traps either but you cannot cover both bands with 1 set
of elements
unless you are using ladder line and a tuner.

A properly designed and built balun has very low loss as long as the
core is not driven into saturation
but there is no reason whatever to use a center balun for a dipole in
the HF range.

: of the bands.

I have run three dipoles without having much of a problem with interaction.
Running a bunch of them could cause real pains - and I seem to recall that
the bandwidth of each dipole is also decreased when you parallel dipoles.

The bad SWR may not be due to the tuning of the dipoles. You may be getting
rf currents on the outside of the coax - which means that the coax is then
acting as part of the antenna - so it would affect the actual system SWR.

To eliminate the currents, use a current balun at the feedpoint of the antenna.
Several possibilities exist, such as a coax coil (add to transmission line
loss), commercial or homemade current balun, or using a bunch of ferrite cores
on the coax.

:> Is the TS-870 actually finding the resonant dipole for the band or is the
:> tuner just doing me a favor, and I am radiating 100 watts out but am QRP off
:> the antenna with a few watts?

A high SWR does not necessarily mean that you are only radiating a small
fraction of the power. There are additional losses due to SWR, but they
depend on the coax losses you get even with a perfectly matched system.

: 20 1/2) and still nothing better.

I assume you mean 2.0:1? The large number is always listed first, or by
itself.

Adjust the main element so that the SWR is the lowest at your center
frequency. If the SWR is still too high, then it means that the feedpoint
impedance is not 50 ohms (see below for another possibility). The
feedpoint impedance is affected by the height the antenna is mounted
above ground - you may need to change the height, especially if it is
less than about 1/2 wavelength above ground.

Another possibility is currents on the outside of the coax. See my post
to a different thread for a brief discussion.

: I don't want traps.

This is a problem, as the feedpoint impedance is going to be high
on even multiples of the fundamental frequency. This is the case
for 80/40 or 40/20. That means you need to use open wire and a
balanced antenna tuner.

: How long would a 1/2 wave dipole be with a combo 80/40?

: I think I only have about 125 feet to work with.

The formula for a halfwave(in feet) is 492/f(in MHz)

Jethro Jumbalaya Twain`s attachment says:
"---CW exchanges can be made with QRM as little as 100Hz away or even closer. Try that with any digital mode..."

Obviously, the relative strengths of desired and undesired signals would determine the feasibility of receiving the desired signal.

Also, the ability of the filters to produce a "single signal" from the morass is crucial.

Simple old fashioned digital modes do pretty well. They can automatically produce perfect copy at 100 words per minute with 18 or 26 channels all running equal strength signals spaced at 170 Hz or 120 Hz, and all operating at the same time.

Spacings and bandwidth of 120 Hz are normal for using the 5-level Baudot code in the space of a voice channel (about 3.3 KHz) while running 100 WPM.

Spacings and bandwidth of 170 Hz are normal for using ASCII in a voice channel at 100 WPM.

A normal voice channel accommodates 26 Baudot channels or 18 ASCII channels at 100 WPM in all channels simultaneously. The Baudot or ASCII channels of this frequency division multiplex are usually FSK modulated. Two tones are used . The first signifies a "mark" condition. The second signifies a "space" condition. Encoding is done by switching between the two tones assigned to a teleprinter channel. Rarely, a channel user will encode by simple on/off tone channel switching. The same bandwidth works for either FSK or on/off coding. FSK is equivalent to FM. On/off is an abrupt form of AM. Performance of FM is usually better than AM, even used for telegraph channels.

With the excellent filters available and normally used with these ancient FSK modems, the performance is good too.

Best regards, Richard Harrison, KB5WZI

Al,
There will be some affect from it not being straight,
but probably not as much as you may think. There would
be a much greater affect if you kept the same shape, but
moved it outside.

F0FFE,
If your speaking about two dipoles in one, with a
common feed point, you figure length just like you were
making a single dipole for that band. So, an 80 meter
dipole will be about 120-130 feet. You may be able to
'squeeze' one into 125 feet.
A balun ~shouldn't~ cause a lot of loss. On the
lower bands, they also can be more trouble than they
are worth though. If it's rated at an adequate power
level, it should work for you fine.

Concrete can explode with lightning strikes. I've seen it on a number of occasions. Several times when it struck a concrete highway. Once when it struck a 50 ft radio tower at a highway weight scale station, jumped from the tower to the house wiring, exited through the electronic scale to the scale platform then into the concrete approach apron where it blew a sizeable chunk of the concrete out of the apron. On another occasion it struck the highway in front of the identical scalehouse across the four lane highway and blasted a chunk of conctete out of the highway slab.
If you see a strange series of potholes in a limited area on a concrete highway in lightning country you can almost assume it is the result of lightning which followed the reinforcing rod. I know of at least four places in this region where that has happened. One was fairly extensive, The moisture content of the concrete surely has a lot to do with how easily it blows. If it's wet it would be a lower impedence current path thus both more likely to be an attractive path and also to vaporize the water in the concrete, causing a steam explosion.

Oh, common mode current doesn't exist at HF?

That's sure news to me.

Odds are that the proximity of the roof is increasing the velocity
factor of the wires making them too long. Taking SWR readings at
the top and bottom of the bands might yield that information and
if you have or can borrow an antenna analyzer like the MFJ-259B,
it will make your trimming job much, much easier.

Check out the All-HF-Band-CF-Antenna on my Delphi web page.
With a 450 ohm ladder-line length of 88ft, it is resonant
on 4.0MHz and 7.3MHz and a couple of higher bands.

> Do BALUNS cause a lot of loss?

Properly designed and applied baluns are near lossless. I
recommend the Amidon AB240-125 balun kit for $9 wrapped
as a 1:1 current balun.

Would the fact that he is using a vertical antenna mean that its
picking up noise in all directions, especially because most noise is
vertically polarized?

Would he do better with a beam antenna on a rotor? (Ignoring for the moment
the impossibility of doing so in his case, being on the ground floor).
What about pointing that hamstick at 45 degrees, or fully horizontal?

A newbie myself, I'm trying to deal with similar issues on 6m. My vertical
is useless.

I'm a newbie and am starting to put together a home station for 40-6m dx.

I've been told that two problems with vertical (base) antennas on HF are:

1. You receive omnidirectional noise, and since most noise is vertically polarized the QRM received is much greater than with a directional beam antenna.

2. You transmit a vertically polarized signal, so only vertical antennas can receive you well. Likewise, you receive vertically polarized signals better than horizontally polarized signals. i.e., verticals can only talk to verticals.

Both seem plausible but how true are they? I thought I'd ask the experts.

Al, the S shape will have a neglible effect compared with the difference (1 or 2 S-units) between an indoor and outdoor antenna.

The S will just cause a small change in tuner setting of which you will be quite unaware because you are unable to do a 'before and after' test. The same will occur whether or not the antenna is indoors or out.

This is true, although the difference depends on your local area. I've lived in a dozen different QTHs, mostly urban, and I have noticed the difference. It isn't huge, but it's there.

Cross-polarization is only a problem for groundwave signals. Once the signal is reflected off the ionosphere, polarization is lost and either horizontal or vertical antennas receive the signal equally well. If you intend to do much groundwave, go with a vertical. Horizontally polarized signals do not propagate well via groundwave. That's why verticals are "noisier".

A counterpoise is a length of wire which, with the antenna wire length,
resonates the whole system to the frequency of interest.

If the counterpoise is as remote from ground as the antenna there is zero
loss due to the counterpoise. It is part of the radiator.

A single buried rod or plate is the most lossy ground connection imaginable
unless the soil is saturated with water.

The lowest loss ground is a set of radials so densely packed as to
constitute a copper sheet 1/2-wavelength or more in diameter.

Let us assume that the interference is really being caused by your very strong 50MHz signal getting into the antenna amplifier via the input connection (I'm sure that this will be the main cause, but it may not be the only problem). However, what you essentially want is lots of attenuation 50 - 52MHz, and as little as possible elsewhere. However....

Using coaxial stubs CAN be very effective, but there are several serious problems with simply adding a simple o/c quarterwave or s/c halfwave stub across the input of the wideband amplifier. These include:
1. The width of the notch will be so wide (even with the lowest-loss coax you can find) that you will also kill the TV low-band (Ch2 - 55.25MHz - will, of course be the worst affected).
2. As well as having a notch on 50MHz, here will be notches at odd multiples of 50MHz (if quarterwave) and all multiples (if halfwave). This may make a bit of a mess of several other TV channels.

The obvious solution to the width problem is to make the notch narrower. With stubs, you can do this by cascading similar stubs, each separated by a quarterwave of coax. This will also greatly increase the depth of the notch. A single stub will give you a notch of 25 to 30dB, and two stubs will increase this to nearly 60dB (I doubt if you'll need anything like this). However, this will not change the 'harmonic suck' effect (although these sucks will also be narrower).

You cannot eliminate the multiple harmonic sucks, but you can move them around so that they do not fall on those frequencies which you want to receive. You can do this (for example) by adding capacitors or inductors in the appropriate places (I won't go into this here).

You will probably be better off with a circuit using only capacitors and inductors. However, there will need to be more to it than the simple equivalent of a single coax stub. I have a typical circuit in mind, but you would have to calculate the values or do some 'jiggling' to values obtained by means of 'inspired guesswork'!

Having said all this, I'm sure that you are not the only one having trouble with 6m hitting TV (antenna amplifier or not). I wouldn't be surprised if there are several off-the-shelf filters which are purpose-made, and don't cost too much. If not, let me know - I'll move to the USA and set up in business!

Ian.

You need to adjust the length of each dipole for the best swr on its band
and let the tuner do the rest. Yes, the rig will radiate on the dipole with
the best match. I've used a three band vertical designed by W6SAI this way.

Good luck,

Bill, W4WNT

In the US the ARRL handbook should be required in every shack. It would save many questions. I have not seen it but think that in England there is a book that is equivilent to the handbook.

As with any book there can be some wrong information. The handbook has been publisned for many years and most of the articals are the same from year to year and if there were many mistakes I am sure they were called to the attention of the ARRL. Micorsoft had an error in the calculator of windows 3.1 and millions of copies were sold and the error carried over to win 3.11 and they knew it. YOu could substract 3.1 from 3.11 and would not get .o1 but you get o. Same for other numbers. There is lots of wrong info in the news groups also.

Many public libraries have a copy of the handbook.

2010. Using two tuners to get on 160?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-28 12:42:12 UTC
From: motorhomer <motorhomer@my-deja.com>
Message-ID: <951434$k7f$1@nnrp1.deja.com>
Source record: 171384

I am trying to tune my 136' doublet fed with ladder line on 10-160 meter bands. On 160 I need to strap the feedline and work it against ground, I am using a Johnson Matchbox on 10-80. Can anyone advise me on whether it would work to just install an antenna switch after the radio that switches in one tuner or the other and connect the ladder line from the antenna to the output of both tuners? Or would you need to disconnect the ladder line to the antenna tuner that is not in use? Also would I need to install another antenna switch to strap the leads of the ladder line together? Has anyone installed a setup like this that can be easily switched without disconnecting wires on the back of the units? I tried running two tuners in series to tune up 160 on the recommendation of somebody and that does not work.

Connecting the two tuners to the feedline would be a problem. There would be an interaction between the tuners and this is not recommended. The problem you are experiencing is due to the fact that the Johnson Matchbox does not have sufficient range to handle the impedance transformation on all bands. If you MUST use two tuners, you should really switch the inputs to and outputs from the tuners.

I would recommend making a double balanced tuner so that you would use use one tuner and it would work on all bands.

However, I'm not sure what types of antennas you desire to use. The doublet could be used on all bands, as a doublet, with the double balanced tuner. When you short the leads together, like you have been on 160, the antenna is operating more like a top loaded vertical. So the tuner arrangement you use depends on what type of antenna you want to use.

Without knowing your intentions, it isn't possible to offer more detail.

==========

I don't have a book handy either but I have to disagree.

If you hook up a piece of metal (cut to length) to the center of your coax it will work quite well with little loss. The trouble with the "learned" authors and technical editors of magazine articles is their propensity for forgetting entirely about orders of magnitude. Their primary concern is with the magazine's circulation figures.

Let's take 5/8-wavelength vertical for 14.15 MHz in conjunction with an adequate ground system of 8 or 16 radials buried in average soil. Antenna height is 42 feet. Assume 14 gauge wire for the antenna.

The feedpoint input impedance is approx 137 - j487 ohms.

If a match to a 50 ohms coaxial line is considered to be of consequence (it depends on line length and its attenuation) then by connecting a 5.5 microhenry coil between the bottom of the vertical antenna and the coax the line will be terminated with a resistance of 137 ohms. This will still leave an SWR = 2.7 : 1 on the line.

If a coil just by itself is considered unsatisfactory then to match exactly to a 50-ohm line there is a choice of two L-networks :-

15pF across the antenna feedpoint with 3.4 uH in series with the coaxial inner.

Or, 2.2 uH across the antenna feedpoint with 37 pF in series with the coaxial inner.

Whether either of these arrangements is adopted or not, the radiating efficiency of the antenna + ground will be about 85 percent equivalent to a loss of 1/9th of an S-unit which no-one will ever notice.

You said you didn't want traps but I'll pass this info on to you just in case everything else doesn't work out.

Send a SASE to: Jack Lindauer, WA6EFM
18881 Brymer Court
Northridge, CA 91326
(818) 831-0515

He manufactures "traps" for a 80/40 meter dipole. The overall length of the antenna is 77 feet. He claims a < 2:1 SWR over the entire 40 meter band and a 100khz tunable segment of 80 meters. Their cost is $19.00 + $4.00 S&H.

Put up a 100' dipole, feed it with ladder line, and use a tuner. The antenna will be slightly longer than a half-wave on 40m, slightly shorter than a half-wave on 80m. The impedance on either band should not be extremely high, so your tuner should be able to find a match. You also might be able to tune it on the higher bands. If you run coax from inside the house to the outside, add a W2DU balun at the point where the coax transitions to ladder line. No pruning, no traps, no exact lengths of transmission line, no balun loss, no fussing. It does require a tuner, but then again, so does a G5RV. 73,

Source record: 171392

I am using a dual tuner setup here. I have placed a tee type tuner in series with my Matchbox. On most bands I keep the tee tuner in the "bypass" position but on 160 and some of the WARC bands flip it into service.

I first tune the Matchbox for the best match I can get with the tee bypassed then bring the tee on line and tweak it to finish the job. Works just fine for me...

A little more knob twisting, but as I've said before real hams twist knobs.

I have used a double balanced tuner that you described and have found
the Matchbox/Tee combination to be better for common mode current
suppression.

Actually you may wish to consider it somewhat like a Tee tuner with a
tunable balun on the output...

This problem is very overstated. If the noise in the direction of the pointed beam is strong, it may well "show" more noise than the vertical. You hear noise on nearly all antennas that are worth a hoot. If they pick up little noise, they probably pick up little signal either. You can see more apparent noise on a vertical at times, but doesn't mean a whole lot if the signal is also stronger. I've run both verticals and dipoles on 40m at the same time. I've never had any real problems with noise. If a vertical picks up 1 s unit more noise than the dipole, but receives the desired signal 2 s units better, the noise doesn't really mean much.
>
> 2. You transmit a vertically polarized signal, so only vertical antennas
> can receive you well. Likewise, you receive vertically polarized
> signals better than horizontally polarized signals. i.e., verticals
> can only talk to verticals.

Not so. By the time the signal has bounced, skewed, refracted, and ping ponged off the ionosphere, the polarity to the other guy 100's of miles away doesn't mean too much. Only when working local line of sight operation doesn the polarity difference mean much. Usually about a 20 db attenuation or so. With sky wave, it's quite possible for a vertical to hear another vertical better then it would hear a horizontal antenna, but that doesn't mean the horizontal antenna is useless. It will still likely do ok also. It could even win under some conditions if it has more gain. MK

> 20 1/2) and still nothing better.
> Any help would be appreciated.

Ken,
I once had trouble tuning one of these things. What I found easiest was to keep the main element at a fixed length, adjust (prune) the length of the open end of the quarter-wave section, and move the wires up or down for minimum SWR. Eventually, I was able to get down to about 1.3 to 1 and quit there. What I found was that the main element does not have to be one half-wave in length, and the transmission line section does not have to be a quarter wavelength. When you put these two together, along with the coax center/shield, all the sections & wires couple together in a complicated fashion.

I might add that the above J-pole was constructed using copper pipe. I tried a cookbook design for a ladder-line J-pole, and was unsuccesful after fussing with the pruning for several hours. I finally gave up, speculating that the ladder line I used may have had a different velocity factor than the one used in the cookbook design. In any event, tuning one of these babies is not a straightforward affair. 73,

Richard,

40 through 6 M is a lot of spectrum to cover. At the low end of the range polarization won't matter a whole lot on transmit since things will get pretty well scrambled by the time they get to the other end. At the high end of that range you may see some polarization effects. It all depends on how you define "DX".

At the higher frequency end of the range you probably will be using beam antennas. Generally for DX you polarize horizontally. There are an enormous number of arguments one way and another about this. The most convincing ones to me is that the mechanics of the antenna generally work out better if it's horizontal.

For a lot of years the ssb crowd has gone with horizontal polarization and the FM guys have used vertical. If you want your antenna system to also work for local contacts you may have to work both polarizations into your plans.

Hope this helps.

Another good J-Pole to build is the Arrow dual band J-Pole. I have built them and they are easy to adjust because if you follow the directions you will not have to screw around with it. Low SWR and extremely heavy duty design. I have seen the plans posted here by Allen before.

Dave -

Traditionally, 6m has been the best way to get the "Worked all channel 2's" award. Various low and high pass filters, even (maybe especially) those that are effective on HF tend to be ineffective on 6m. The main problem is that 6m sits right in the middle of what would've been TV channel 1. TV sets tend to have RF front ends that are very poor in terms of strong adjacent channel signal performance. Also, TV's are usually poorly shielded (how many 15KHz harmonics can you count?) so 6m will be picked up by the power wiring and the TV circuitry itself!

What to do? I can't say what if anything will work for you, but here are a few things to try. I'm assuming that your 6m rig is clean, so my suggestions all apply to the TV system. 6m harmonics should not be much of an issue even if present because they impact only one VHF TV channel (11 I think). The basic goal here is to reduce the 6m signal strength at the TV's, TV amp and TV antenna.

1. Move your 6m dipole as far from the TV antenna as possible. The dipole is physically small (10' or so long), so this ought to be easy to do.

2. Keep the 6m and TV ant cables as far apart as possible. You say that you get an SWR of 1.3:1 WITH a tuner? Better to adjust the 6m dipole so that you have a low SWR *WITHOUT* the tuner, assuming that you're feeding the dipole with coax. If this turns out to be the problem, a "current choke" balun at the dipole may also help. If you're feeding the dipole with twinlead, you need to be more careful about what is near the twinlead's path from the antenna to your radio. In either case, the idea is to prevent the 6m antenna feedline from radiating.

3. Orient the 6m dipole so that the TV antenna is directly off the end of the dipole. Putting the TV antenna in an antenna null is the simplest way to reduce the 6m signal level at the TV antenna.

4. Choke/filter the AC power lines feeding the TV amplifier and the TVs. Radio Shack (and others) sell a ferrite core for this. I think they're fairly inexpensive - $3 for 3 or so...

5. Build quarterwave stubs tuned to 6m and install them at the antenna inputs to the TV amp and the TVs. This will selectively reduce the 6m signal level to the amp/TVs. It's possible that the only one you'll really need is on the TV amp - assuming that it's the only box being overloaded. If channel 11 is used in your area, the stub may also affect it. If so, the stub may not be a good idea. (BTW, the halfwave stub

suggested elsewhere would also affect the 2nd harmonic of 6m. Lucky for you, 100MHz is not a TV channel. Unlucky if you're using the same antenna for FM broadcast!)

Good luck. Enjoy 6m!

Great answers! Thanks for the advice. My original thinking was to get a vertical like the MFJ 1796, which covers 6 bands 40-2m, and would fit nicely on my roof. It looks like that may in fact be the right way to start.

Then, if I can't get the coverage I want on 10m and 6m, to get a separate beam antenna. I am concerned about local QRM, especially on 6m, because I do live in an big urban area.

Thanks for the help

I've done the same as Dan on occasion. What's going on (I think) is
that the "tee" is transforming the antenna impedence from whatever
it is to some intermediant impedence. The matchbox then transforms
the intermedient impedence the rest of the way to 50 ohms. What Dan
has is a single matching network that is the composite of the tee and
the matchbox. It's more complicated to adjust but not so much that
it can't be done. On 160m, presumably the coax between the tee and
the matchbox is short enough that it's not really a transmission line...

The only issue I see is that one or both tuners are operating at other
than their design impedences and so may not have appropriate spacing
for higher voltages (possible arcing) of insufficent wiresize for
higher currents (higher resistive losses).

Glen,

You are correct, It is just a two stage tuning arrangement. However,
tuners such as these (one the other or both) do not have a fixed
designed impedance rather they tune a range of impedances.

Additionally, the coax between the tuners is indeed a transmission
line.

The system works fine.

Message-ID: <3A746EEB.CDD37EAA@oio.net>
Source record: 171408

Richard,
1. Vertical antennas are 'noisy'. If there's any 'noise', you'll
probably hear it. This ones correct.

2. There is a difference in signal level when polarization isn't
the same, at least before a signal is reflected once. After
one 'bounce' polarization doesn't make a lot of difference
because it 'changes'. I wouldn't worry too much about what
the polarization it.

Cecil, W6RCA wrote:
"All that matters is if it is efficient enough to get the job done."

True. For all I know, the archer`s shaft may move mass more efficiently than the gunman`s bullet.

The question is, does it beat the competition? Survivors are those best adapted to their environments. You wouldn`t want to bring a bow and arrows to a gunfight in most circumstances. American Indians who tried that usually lost, with a few notable exceptions, of course.

Best regards, Richard Harrison, KB5WZI

2040. Screwdriver antenna for apartment

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-28 23:02:38 UTC
From: jason_hsu@my-deja.com
Message-ID: <9528eagcs1@nnrp1.deja.com>
Source record: 171414
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.dx,rec.radio.amateur.equipment,rec.radio.amateur.misc

Some of the questions I have include:
1. Can I use one if I only have 8 feet of clearance on the small patio (8 feet wide, 8 feet tall, 6 feet wide) outside my sliding door? Is it possible to mount the antenna at a slant? I want to hear about any creative solutions from you.
2. What type of mount/tripod would be appropriate? (I don't have a railing.)
3. How quickly can I assemble and disassemble the antenna? (For stealth and security reasons, I need to remove the antenna when I am not operating.)
4. Which versions (original DK-3, ElectraSlide, etc.) of the Screwdriver are most appropriate for me? What advantages do the more expensive versions have over the original? Can some versions (like the D&K KH-600 HF MOBILE ANTENNA) really operate on 160m?

SOME BACKGROUND:
I am seriously considering a Screwdriver antenna for operating HF from my ground floor apartment (no big trees or bushes close enough to conceal wires and keep them out of the way of people or dogs passing by). A mobile antenna would be less cumbersome to work with than a big wire antenna. The Screwdriver seems to be the best antenna for me.

I have had modest success with Hamsticks I am borrowing, but I know that Screwdrivers are more efficient. Also, Screwdrivers are multi-band and are easier to tune (due to the automatic tuning aspect). Has anyone used a Screwdriver antenna for non-mobile operation?

I was considering a Texas Bugcatcher, but I am not sure about the quality of the version from Texas Radio Products, and the version from GLA Systems is too expensive. Screwdriver antennas are almost as efficient, and several versions sell for near or below $200.

Because the insulated wire may have a velocity factor appreciably different from 1, depending on the dielectric constant and thickness of the insulation.

Let's have a vote on it.

Hands up all those who think the velocity of em waves in metals is 5%
different from the velocity in free space.

Source record: 171417

While we are voting- lets settle the "flat earth" question, too.

The 5% figure many people use to apply to correct the length of an antenna is supposed to be an end effect, and was said to have been determined by measuring the resonant frequency of a dipole in the alley behind the ARRL station. I have seen it applied as an "end effect", ie, on multi-wavelength antennas, applied only once, to the total length.

"for what it's worth"-Your milage may vary"- "put this in your pipe and smoke it" - "why?" -"etc"

Comment, Reg?

Hi all and thanks for reading my post

I have been out of AR for 14 months (due to an accident not loss of interest) and am now looking to get back into it.

I am looking at building a lot of my own gear this time around and one project is an antenna rotator. Although I have searched high and low on the internet, I can not find anyone that has built a rotator system from scratch. I have found a direction indicator but that's all.

Has anyone built or know of an article that describes building an antenna rotator? If so could you please point me in the right direction or send me a scanned article, but please email me direct after you have removed the SPAMJAM.

Just go to:

http://www.nucleus.com/~field/

and download Coaxtrap.

It's a Windows based program that lets you design N4UU style coax cable traps
for practically any HF frequency, coax and pipe diameter. Sure wish I'd had it
when I was making mine!

Look at High Sierra -- http://www.hsantennas.com//index.html They have
a number of mounts for deck use or portable operation. They might have
answers to all your questions...

I believe Lew McCoy mentioned he ran a High Sierra against a metal
roof with good results...

You'll probably need a counterpoise, but that'll just be a long piece
of wire you can run through your apartment...

Glenn,

Your last question (in a string of questions) to William was:
"Can you lower yourself to my level and try and
help me out William or do I need to read a book instead?"

William's answer was: "nope."

Where is the problem?? (Other than your demeaning inclusion
of the phrase "can you lower yourself to my level")

Why don't you, as a General class licensee, have enough basic
understanding of antennas to know that you aren't missing anything -
that the original poster needs to learn the fundamentals? Why didn't
you answer his question, rather than engaging in an unprovoked
attack on William? There was nothing rude about William's post,
your attack was uncalled for, and you owe him an apology.

Reg:

Without checking the books, here's my vote.

I believe that the speed of em in (on) metalic conductors is very much closer to the speed in vacuo than the 5% variance, in fact the difference should be almost imeasureable, however the speed of em radiation in (through) dielectrics is substantially slower.

So that, if transmission lines or antennas have dielectric insulation such as found in coax or on window ladder line, then the em waves on or over those "insulated" conductors will travel slower than in vacuo.

That's why the velocity factor of coax is substantially less than 1.00.

Is this right?

What exactly are you referring to as "common mode" and why is it necessary
to use a balun??
There is absolutely no need to use a balun at HF unless you are concerned
about upsetting a directional pattern
and of HF few antennas would be directional enough to care.

If you are running a beam, directly feeding a yagi with coax you can coil
a few loops of the coax to choke off any
currents on the outside of the shield.

Now can you tell me how many path(s) exist is a piece of coax feeding an
antenna???

A second antenna used for receive would be a possible answer, A small magnetically shielded loop that
could be rotated to null interference while staying relatively non directional to skywave signals.

Most skywave is horizontal polarized, On V/Uhf you can
exceed 23 db loss using cross polarization
On HF it is a different story.

>

>
>
> Both seem plausible but how true are they? I thought I'd ask the experts.

Efficiency is a sore point needing a good ground to work against (1/4 wave)
If the vertical exceeds 5/8 wave high angle will result rendering the vertical
useless for much serious also if you wish to talk local within a few hundred
miles look elsewhere verticals have little high angle radiation, just what you
need for short skip on 1.8 to 7 mhz. You may talk to your buddy 100 miles
away every day on 80 and half way across the world once or twice a year unless
you are a low band DXer and have the resources to install the vertical systems
needed and no a 23 foot all band will not do.

Anything covering 40-6 meters is a compromise and I would be dubious
of it, a combination of 2 or 3 antenna's specialized to your needs would be a
better choice if you are a serious DXer!

Are there antenna's other than metal?? and yes there is a velocity factor and
that is why traveling wave antennas
start lousing gain after an optimal length, The received wave is not in phase
with the wave being propagated
down the antenna and gain starts to decrease.

Open wire feeders may have a velocity factors of 97% ladder line maybe 88% coax
may run from 83 to 60%

There are three paths.

The term I used was "common mode current". That's the name given to
the unwanted current flowing on the outside of the coax's shield.
Besides effecting antenna patterns it can also cause in increase in
RFI problems and other things such as hot microphones and the like.

It is considered good engineering practice to include some form of
choke/balun on *any* antenna system using a coaxial feedline. It can't
hurt and will only help.

2064. ground screen vs. radials

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-29 05:37:48 UTC
From: Darrell <upson@my-deja.com>
Message-ID: <952vjc$25p$1@nnrp1.deja.com>
Source record: 171338

Does anyone have any experience or knowledge of vertical antenna efficiency comparing a solid ground screen, like hardware cloth or chicken screen, to using radials? Seems it might be cheaper and easier than laying out 120 copper wire radials.

I've been looking at the Bilal Isotron 20m antenna for travelling. For 20m and higher these things aren't even loops -- more compact than that. Apparently no radials are needed and some hams have said that they work well even close to the ground.

If you've had any experience with them please let me know how well they work. I'll probably run it off a QRP rig.

Thanks, Pete KATZK

Message-ID: <AI7d6.25381$OD.9633678@typhoon.snet.net>
Source record: 171339

The ARRL Antenna Handbook goes into this in quite some detail. Basically, with individual radials, you reach a point of diminishing returns at far less than 120. They also mentioned that the ground screen would cost more and be an overkill since it would basically cover the same area but with a much denser pattern due to the closeness of the 'weave', so to speak.

120 radials are used by broadcasters who also use a ground screen very close to the base of the antenna for a radius of several yards. Amateurs can get away with a far simpler system, like 32. Experiments indicate that as few as 4 for each band are enough to get good ground conductivity. I ran 12 wires across my back yard, cut them all at the base of the antenna, and used a hose clamp to connect them all to the mast of an HF9V. I got very good results according to an MFJ269 antenna analyzer.

Hope this helps.

Darrell,
I don't have personal experience with both screen and
wire radials, but know someone who does. He seems to think
that wire radials are cheaper than using screen, but both
do about the same thing. He had a lot less than 120 radials,
something like 30 if I remember correctly. Also used 4 strips
of fencing (same as 8 from the center) and they worked okay.
If you already have some fencing, and had to buy the wire,
it would probably work out the same as far as effort and $$
went. If you have to buy the fencing, the wire is definitely
cheaper. Burying the stuff is something else, especially the
fencing!

Pete,
I've had the 10 meter Isotron, and it works
comparably with a 1/4 wave groundplane. It wasn't
the easiest antenna to tune, and the higher it is
the better. For a 'make-do' antenna I'd say it
should work well enough till you can get up a 'real-
live' antenna, or for use in limited space areas.
For QRP, I think you'd be wasting your time, but
if that's all you can do, then why not.

jason,
1. Yes, probably, to both questions. Just have to try it
and see.
2. Your imagination is your only limit. How about a large
flower pot, fill it with concrete with a pipe standing up
in the center of it. Mount the screwdriver on a pipe that
would fit into the one in the pot. Paint the concrete
green and leave it on the patio. (tell them your plant died)
3. Beats me, just depends on how much you practice (LOL).
4. I think 'which' antenna you choose would be more a matter
of how much you want to pay for it. The 'High-Searas'(s) are
nice, but I don't think they're worth the cost. Up to you...
4A. 160 meter operation is going to depend on the length of the
'whip' you use, and if you use a capacitive hat. It's
certainly possible.

Yes
I had a friend in the Ukraine who used a geared motor attached to the back
axle of a Lada to turn his beam.
It could have turned the whole block of flats.

I used to use a heavy duty stepper motor to turn a VHF beam in my attic
(weight taken off motor by suspending antenna from a string, but I have not
seen any stepper motors that would be up to the job for a long time.

Just an FYI - I added the plate to the back side of the glass and hooked up a small gnd wire to the plate. The SWR changed radically. Before, I had cut about 2 inches off of the whip to try to get a resonable SWR on all 40 channels (CH 1 was 1.5:1 and CH 4 was 2+:1) - And that was with the whip at it's shortest. With the plate installed the SWR on CH 1 is now 1.4:1 and CH 40 is 1.2:1. (Kind of the opposite), and now the whip is fully extended! I think I could have used an extra 1/4" or 1/2" of whip. Pitty I cut it. - Live and learn.

Regards.

Richard:

The myth here is that noise is "vertically" polarized. It is not. Natural noise is considered to be randomly polarized.

In HF communications, there are several significant sources of natural noise (I will leave man-made noise out of this discussion): atmospheric noise, cosmic background (galactic) noise and ground noise. The amount of natural noise an antenna introduces into the communications link is more a function of the antenna's radiation pattern than its polarization. An antenna introduces noise into the communications link simply as a function of how much noise it "sees". Noise sources are defined in terms of temperature (degs Kelvin) and the amount of noise introduced by an antenna is defined as the antenna noise temperature. The relative noise temperature of the noise sources mentioned earlier varies with frequency but ground noise is considered to have a noise temperature of 290 K - 320 K, atmospheric noise is considered to have a temperature of 10^6 K - 10^8 K(at HF), and galactic noise is considered to have a noise temperature of 10^5 K - 10^8 K (at HF).

From this, it is clear that an antenna with a radiation pattern that "sees" more of the sky, will introduce more noise than an antenna with a radiation pattern that "sees" less of the sky. If a vertical antenna introduces more noise than a horizontal antenna of the same efficiency and gain (in the direction of the signal source), it is solely a result of the fact that the vertical must "see" more sky noise (it is not a polarization issue). Antenna efficiency is important because two antennas with the same pattern will introduce different levels of noise if their efficiencies are different. Antenna gain (in the direction of the signal) is also important because it affects the signal to noise ratio at the antenna. For example, consider two horizontal antennas - one a dipole, the other a directional beam. If both antennas have the same efficiency and see the sky equally as

a percentage of their total radiation pattern, then they will both have the exact same noise figure and introduce the same level of noise into the link. However, the beam will provide a better signal to noise ratio (and sound less noisy) because it picks up more signal.

Sorry for the long winded answer but I thought I would clear up the assumption that noise is vertically polarized.

Hi gang
has anyone ever made a 5/8-wave broadcast band fm antenna (88-108 Mhz) for mobile use? It seems like it would be advantageous even though the frequency spectrum is quite wide (20Mhz on roughly a 100Mhz center). Any thoughts on this would be appreciated such as:
would you be better off designing the 5/8 for the middle, hi-end or lo-end of the band? ....how could the impedence matching be accomplished? .... at what angle should the maximum pickup be?
thanks
Doug

The other posts recommended the 108" or 102" RS whip antennas,
but something shorter is also available. I used a RS antenna that
was only about 36". It comes with a loading coil in magnetic
base mount. It's made for CB but adjusts easily for 10 Meters.
I used it mobile, from Phoenix, for many years and had a
lot of good luck. Running my HTX-100 in the high or low
power mode I was able to easily work the mid-west and east
coast. This, of course, is very dependent on the state of
10 Meters at any given time, but a short antenna does work.

As for building one, take a look in the ARRL handbook. There
is always a section on mobile communications and information
on building mobile whip antennas.

A thin linear dipole will be resonant at a length of 3 - 5% less than the
1/2-wave length because of the "end effect". Wire diameter will change this
% value. The 1/2 wave dipole is a resonant antenna not a traveling wave
antenna. The "velocity factor" or phase velocity are not relevant for
resonant antennas.

Your statement is correct but misleading because it is incomplete. Both natural and man-made noise are randomly polarized AT THE POINT OF ORIGIN, but horizontally polarized noise is rapidly attenuated by traveling over the earth (groundwave) while vertically polarized noise is not. Thus, verticals appear to be "noisier" because they pick up the (un-attenuated) vertically polarized noise. Horizontally polarized antennas respond primarily to the (attenuated) horizontally polarized noise and therefore appear "quieter". It really has nothing to due with the antenna itself, just how much noise energy reaches them.

For skywave noise, there is little difference between the two antennas.

Absorption of horizontally polarized signals is the reason AM broadcast stations invariably use vertical polarization. They WANT groundwave coverage and horizontal polarization would be ineffective.

Richard Friedman wrote:
He had been told vertical antennas have two problems.

Omnidirectionality does not discriminate against noise, which is mostly vertically polarized.

And, vertical antennas can only talk to other vertical antennas.

There is some truth in the above. Directional antennas improve signal over noise by directionality. Most noise seems vertically polarized, but could be horizontally polarized. It depends on the source.

Vertical antennas talk well to horizontal antennas via the ionosphere, or via wave tilt caused by ground loss under a horizontal wire, or by whatever else may scramble polarization. But, ideally, similar antennas on both ends of a sky-wave circuit may produce the best results. They have complimentary characteristics. What`s best for one is best for the other (forgetting noise and considering only signal).

I have erected many shortwave broadcast curtain arrays. All used horizontal polarization which is standard for the business. B. Whitfield Griffith, Jr. in "Radio-Electronic Transmission Fundamentals" has this to say about that:
"The radiating elements may be either vertically or horizontally polarized, but horizontal polarization usually seems preferred because of its involving less absorption at earth reflection than is the case with vertical polarization."

Over ocean water, conditions are different. But, I`ve never seen a shortwave curtain array over the ocean. I`ve seen many in various SW broadcast plants around the world (all horizontal), but someone reported a vertical with a corner reflector used for SW broadcast somewhere near Dallas. This is the proverbial exception.

Hi Bill,

Your last paragraph on AM transmission is certainly correct but it is a solution to a slightly different problem than considering natural noise sources and antenna noise temperature.

In all cases, the level of total noise seen by an antenna has everything to do with the antenna. Specifically, it is a direct function of the antenna's radiation pattern and the antenna efficiency. All antennas respond to noise as a direct function of their pattern shape and the total contribution of

noise from all noise sources they see.

In HF communications, the significant source of noise is skywave or atmospheric noise. The portion of skywave noise propagating along the earth horizon will experience more attenuation from atmospheric absorption and ground losses than other skywave noise. Additionally, the noise contribution from the earth horizon path represents only a very small portion of the antenna's overall pattern and it is likely that this noise component will be over-shadowed by the remaining skywave contributions.

The other night I performed the following and it worked OK. I took a 49 inch whip and attached a coil made of 10 turns #12 wire which were wound round a pencil. I stretched it out to approximately 2 inches. I moved the center of the coax one turn at a time away from the antenna till I saw a 1:1 SWR. Using this contraption on my desktop with my barefoot Icom IC2 A/T I was able to work a repeater 40 air miles away with some slight noise. I did not ground either the coil or the outside sleeve of the coax. I will continue to experiment maybe grounding first one then the other of these leads to see if it makes any big changes.

OK. ASCII and Baudot need start-stop bits. Morse doesn't.

>Many of the instruction set characters needed don`t
> exist in Morse code.

They also don't exist in Baudot.

> Morse would then require special character
> groupings to convey the instructions represented by a single
teleprinter
> character.

There are a large number of Morse characters that are not generally
used. Characters like parentheses and quotation marks do exist for
Morse. Only the exclamation point is absent (!)

> Morse goes down the efficiency tubes on that basis alone.

Sorry, you haven't made your "efficiency" case at all.

> Ask
> yourself: Why don`t machines use Morse if it is efficient?

Several reasons:

1) Mechanical simplicity - When the first teleprinters were designed,
the code used was tailored to simplify the mechanical design of the
teleprinter. That's why Baudot has only upper case letters.
2) Security - using Morse would have meant that operators could read
the teleprinter messages without a teleprinter.
3) Standardization
>
> The usual telegraph machines (Telex) use a standard 5-level Baudot
code.
> Normal operation is at 60, 75, and 100 words per minute. The bit rates

> for these speeds are: 45, 57, and 75 bits per second.

OK - let's look at that for a moment.

The standard Baudot code used in teleprinters has a start bit, five data bits, and a stop bit. No parity or other error-detection or -correction features. At 60 wpm, the start and data bits are 22 milliseconds long and the stop bit is 31 milliseconds long - so each letter or number requires 163 milliseconds. Using the "PARIS" test, we find that it takes 978 milliseconds to send PARIS once, so the speed is just about 61 wpm.

Now compare this to Morse with an identical dit length of 22 milliseconds. The word "PARIS" takes 1100 milliseconds to send in Morse, so we get about 55 wpm. Baudot is therefore a little faster than Morse, by the Paris test. But only by a few percent.

But there's more to it! Baudot does not have separate codes for letters and "figures" - there are special shift characters required. To send something like the callsign N2EY in Baudot requires SIX characters, not four (it would be sent as "N [figs] 2 [ltrs] E Y" in Baudot). Also, extra characters like carriage returns and line feeds are needed in Baudot teleprinter operation.

In RTTY radio use by hams, it was common to send control characters twice to be sure they weren't dropped, so the receiving station didn't print garble. One quickly got used to hitting CR, LF, FIGS and LTRS twice "just in case". Any speed advantage of Baudot vs. Morse was lost in such practices, but it was better than wasting paper because a LTRS was dropped. (We used to run a Model 19 at the college station - ah, the smell of hot machine oil in a small radio room on a spring morning....)
>
> 7-level and 8-level ASCII codes often run at 100 words per minute,
with
> a pulse rate of 110 bits per second.

And they use more bits to send the same data as Morse.
>
> Telex uses 120 Hz of bandwidth to convey 100 words per minute with
> either FM or AM carriers.

How do you get those numbers? For FSK, the shift must be known. For OOK, the keying waveform must be known.

> SSB could be used to shrink this bandwidth.

How? There is no such thing as "SSB FSK".

> ASCII needs 170 Hz of
> bandwidth for 100 words per minute.

And as we have shown, Morse would beat that slightly.
>

> But you can say much more in 100 words of ASCII than in 100 words of
> Morse because of all the 1-character instructions available in
> teleprinter code.

True to a limited extent - IF you used those characters. In plain
language, the advantage is lost.
>
> The inherent efficiency of teleprinter codes derives from their equal
> length code elements and their extended instruction sets.

You still haven't defined "efficiency".

And note this: PSK31 beats both ASCII and Baudot FSK by sending 50 wpm
in 31.5 Hz. Part of this is the use of PSK instead of OOK or FSK. But a
BIG part of PSK31's advantage comes from the fact that it uses a
Hoffmann (sp?) coding - the most frequently-used characters are the
shortest ones, and the less-common ones are longer. Just like Morse.
The inefficient ASCII is translated into the PSK31 code for
transmission and translated back after reception.

The inventor says he got the idea from his knowledge of Morse.

Steve, VE9SRB wrote:
"The "velocity factor" or phase velocity are not relevant for resonant antennas."

The 3 to 5% reduction in physical length of a resonant wire is as steve says "end-effect", mostly. The voltage tends to double at the open-crcuit wire ends as it would at the far end of an open-circuit transmission line (Ferranti effect). The incident and reflected voltages are in phase and add. This is not magic. The current is interrupted and its energy is transferred temporarily to the voltage wave. Higher voltage causes a larger capacitive effect. (Remember the "Miller effect" in an amplifier stage?)

That`s not all that`s like a transmission line in a resonant antenna. Terman says that current distribution on a fine wire reonant atenna is nearly the same as on a transmission line. I believe that relates to propagation velocity too. But the the impedance and admittance values of the antenna are quite different from a transmission line, usually. So, the velocity of the wave won`t usually be slowed by very much on an antenna. The phase lag won`t be much greater than in free space along the wire.

You can run them either way, grounded base coil that is tapped, or an
ungrounded series coil. There are advantages to both, depending on what
you are wanting to do. An ungrounded coil can be used on other bands.
Say a 10m 5/8 gp with a series coil can usually give a decent match on
30m as a 1/4 GP. With the grounded coil, this won't work. But if you are
in a heavy lightning area, a grounded coil could be a good idea. It
places the antenna at ground potential, much like using a grounded
driven element on yagi. But overall, I prefer them ungrounded so I can
use on other bands. MK

> they want!

But Dean, there is nothing to "earn". The spectrum is already
ours (ie, public property) so the government isn't *giving*
anybody anything they don't already own. We must all accept
restrictions, for safety and to maximize use of this public
property, just a we accept restrictions on which lane to drive
in but there is no reason to "earn" what we already own. We
accept driving tests to prove we can operate a car on public
roads with reasonable safety, not to "earn" the right to drive.
So I ask again, how can one justify requiring the people who own
the spectrum to learn an archaic mode of communication (Morse)
in order to use an entirely different mode (Voice). It might be
reasonable to argue that some parts of the spectrum should be
set aside for Morse on the basis of the numbers of people who'd
benefit, and to require proficiency before using those bands,
but the current and previous schemes are indefensable.

We're talking apples and oranges. I have no problem with bow hunters having a special bow-only season, nor with folks who enjoy code having unique code only parts of the spectrum. My objection is, and always has been, requiring people with no interest in code to learn it anyway. That's akin to requiring those who hunt with guns to demonstrate skill with bow and arrow before being allowed to hun with a rifle.

Yes. I made a 4-element one and used it for a while. got the
dimensions from a magazine article (approx 1/4 wave to a side).
Used 1/4 inch OD plumbing copper tubing for elements and scraps
of plastic water pipe for the boom and supports.

Some amount of current flows from the center conductor of the coax to the antenna. An equal and opposite current flows on the inside of the coax shield. If you leave the coax open circuited at the antenna, the current from the inside of the shield "spills over" the shield at the open end and flows down along the outside. So the outside of the coax shield becomes the other half of the antenna. This will sometimes work, depending on the length and orientation of the coax, but it can be hard to duplicate. If you're running much power, it can also aggravate interference problems if the coax is routed close to other wiring. You can verify that it's happening by watching the SWR as you coil, move, or grab the coax. This is also one of those cases where the SWR mysteriously changes as you change the feedline length (because you're also changing the antenna length).

Hi Jim,

Beg to differ, OM (both of you). FSK is sideband. Receive tuning is offset to the center of the shift, but the principle modulation is something like +1.7 Khz +/- some frequency around that (I think I saw the figure 400 Hz?). It's been a long time since I've taught RTTY fundamentals. Most receivers of that era (early 70's) introduce the offset to the tuned frequency just like the offset for CW. This is simply to fit the off-center sidebands into the IF filter range.

If I recall correctly, you can send FSK on either side of the suppressed carrier. I was teaching the operation and troubleshooting of the Collins AN/URC-32 and the choice of wrong sideband could lead to some interesting TTY operation with what appeared to be good signal levels and waveform shapes (I think the converter was an URC-17c, at least that is the nomenclature that comes to mind through that fog of the distant past). This of course was a troubleshooting problem for the Lab portion of instruction. The student was expected to note the polarity of the signal during the Mark condition.

Thanks for your input, Doc. The reason for my question is that I'm looking for antenna ideas for my RV (Indeed, I posted a question on here some weeks ago).

I have a 1/4 wave groundplane that I use at home and am very satisfied with it. In fact, just for fun I cranked down my power to 3 watts on my IC756 this weekend to see how I might do. Much to MY amazement (although not the dedicated QRP fans I'm sure) I had three very nice QSO's each about 1000 miles from here. But, admittedly, it's base is up at about 27 feet and has five 1/4 wave radials. I can't get the height or the radials on my camper. Nor do I want something sticking up 16 feet or so.

My original thought was that I'd put up whatever antenna I had when I made camp and take it down for travel. But the 20m Isotron seems so small and simple I might just be able to leave it up.

As for the rig, I'm thinking of getting the new FT-817 to carry in my pack as well as use in the RV. Of course, on the trail I'll most likely use a dipole hung between branches.

Before you go too far with it, you might try a wire Yagi. I made such an antenna for 10m some time ago by just stapling the wire elements to the trusses in my attic. Obviously I can't rotate it, but it might give you an idea of how one will work. Mine works fine, BUT it does seem to pick up a lot more noise than my other (outside) antennas -- from the house wiring, I assume.

I use both EZNEC and NEC-Win Plus+. Both use the NEC2 engine. On identical antennas I have found them to be in very close agreement - usually varying no more one hundredth of a dB or so...

If you are getting a wide variance I suspect your trouble may be elsewhere.

NEC4WIN uses the MININEC engine and can give different results compared to EZNEC or NEC-Win Plus+

Message-ID: <3A760AE7.15C41D59@eznec.com>
Source record: 171288

Sorry, the original message didn't get through. Let me elaborate a little on what Danny said.

I've occasionally had reports of different answers from two different NEC-2 based programs or two different MININEC based programs. In virtually every case, the difference occurs in a situation where a very small change in the antenna can cause a very large change in results. A common case is in looking at the impedance of an antenna near antiresonance (like a full wavelength dipole or half wavelength monopole). A very small difference in source placement can cause a pretty radical change in reported impedance for these antennas. Some programs do automatic segmentation, resulting in small differences in source placement from one program to another unless the segmentation is manually forced to be identical. This is enough to cause noticeable differences in results in some antennas. Even small differences in the order of calculation, the precision of internal variables, and so forth can show up under these circumstances. But for the vast majority of antennas, programs with the same calculating engine will, as Danny says, produce virtually identical results.

MININEC and NEC-2 results can differ quite a bit because of fundamental differences in the calculating engines. MININEC, for example, assumes that the ground is perfect when doing impedance and current calculations. (EZNEC can be made to do this also by specifying the MININEC-type ground model, but it can also be prevented from making this substitution.) This causes MININEC to give increasingly wrong answers as a horizontal antenna is made lower and lower over ground. MININEC also can give pretty dramatically wrong answers for close spaced parallel wires, and significantly wrong patterns for quads and other antennas with parasitic elements containing wires connected at an angle. MININEC also has a known "frequency offset" problem where long Yagis will show the correct pattern at a frequency a bit offset from the frequency where the pattern actually occurs. On the other hand, NEC-2 doesn't do well with small loops, creates a small error when wires of different diameter connect (which can cause significant pattern errors if in a parasitic element), and is very sensitive to source placement and to segmentation of close spaced wires. So while you can expect NEC-2 programs to agree with each other and MININEC programs to agree with each other (except sometimes when very small changes in the antenna make very large changes in results), NEC-2 and MININEC can more easily disagree with each other. As Danny said, NEC4WIN would be the odd man out in comparing the three programs mentioned in the original posting.

None of these programs is perfect, and each has significant limitations and peculiarities. Successful modeling depends on knowing what these

are. You can find more information about NEC-2 limitations in the EZNEC manual (which is also included with the demo version) and in the excellent series by L.B. Cebik, W4RNL presently running in QST. MININEC's limitations are described in "MININEC - The Other Edge of The Sword" in February 1991 QST.

2114. Building a Windom or OCFD info please...

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-30 01:40:13 UTC
From: Mike <KA1DRZQRM@worldnet.att.net>
Message-ID: <1Yod6.17364$cN.933097@bgtnsc07-news.ops.worldnet.att.net>
Source record: 171289

I am considering building a Windom or an Off Center Fed Dipole. I am looking to see if anybody has any practical experience with these or can reccomend a source of information. I hare read the Windom/OCFD articles in the current edition of the ARRL Antenna Book and the OCFD section in ARRL's More Wire Antenna Classics-Vol2. I am planning on cutting it for the 160 meter band primarily for use there and on 75 phone. I should be able to hang the feed point height of 40 to 45' or so, and maintain a decent flat top configuration with reasonable sag.

I am interested on advice on feeding the OFCD. It appears many feed it with coax through a 4:1 Balun which provides a better match- sometimes a 1:1 swr point, but a 6:1 (sometimes used on commercial models) give a wider bandwidth but not always a 1:1 spot. Another version the appears circa 1950's is to feed it with twin-lead through a 4:1 balun. Could feeding it with a specific length of twin lead or window/ladder enhance vertical radiation?- Similar to how the Radiator section of coax on the Carolina Windom radiates vertically.

I saw a design in the first volume of ARRL Wire Antenna Classics where the builder fed a 40 meter OCFD with ladder line in odd multiple of 1/4 wave (allowing for velocity factor) to get it to load on the odd harmonic of 15 meters as well as the normal (for windom-like arrays) even harmonics. He simply had to change from the 4:1 balun to a 1:1 balun to use it on 15 meters. I am not looking to pick up even harmonic bands, but would be interested if the addition of a resonant length of window/ladder line could enhane vertical radiation on 160 or 75 (or any other band as a bonus).

Any advice, instructions, or suggestions appreciated. Please post here or Email direct. Remove the QRM from my address to email directly.

73,
Mike

Dornbos wrote:
"Has anyone ever made a 5/9wave broadcast band fm antenna (88-108 MHz)
for mobile use?"

Millions have been made and used. They were primarialy made for AM reception but used for FM as well. Telescopic car antennas were the norm until a couple of decades or so ago. In those times, happiness was a 100-incher, often called a "long-ranger".

At 100 MHz, the wavelength is 3 meters. A 1/4-wave whip is 75 cm or 29.5 inches (with no reduction for end effects). 5/8-wave is 74 inches. 1/2-wave is 59 inches. So, with plenty of long rangers manufactured which extended to 100 inches and collapsed to a small fraction of that, there has been no shortage of possible ready-made 5/8-wave antennas for FM reception.

You could also trim a 102-inch CB whip to 74 inches for a 5/8-wave FM whip. If you wanted to suppress the secondary lobes that start to appear at 5/8-wave, you could further trim the whip by an additional 3 or 4 inches to compensate for the end effect.

Best regards, Richard Harrison, KB5WZI

This has been on there for a long time. It is apparently the GAP version
of the CFA. I see there is a patent number associated with it. However,
everyone knows that a patent number only means you spent lots of bucks,
and says nothing about how it works.
Since this has been on there a long time, but GAP has made no noises
about it yet, I really wonder if they remember it is there. I wonder
what a query about it would get?

Good plan. This one happened to be built on the highest spot in the
county, and was a virtual lightning magnet. I was the guy they called to
clean up after the strike had fried the radios and speech amps.

Hello Richard,

No, FSK is a form of FM, which is a form of "angle" modulation. As on-off keying (OOK) is to AM, FSK is to FM. More below.

> Receive tuning is
>offset to the center of the shift, but the principle modulation is

Sorry if I wasn't clear in my previous post - I let brevity supersede clarity. I'll have another go:

Frequency shift keying is just that - the frequency of the transmitted wave is shifted by the keying signal. ASCII, Baudot, Morse, and lots of other codes can

be sent by FSK. The simplest way to generate it is to build a continuous wave transmitter (one that puts out a carrier of constant amplitude) and shift the frequency of one of the oscillators in the transmitter.

But that's not the only way to generate an FSK signal. An SSB voice transmitter has the property that if you put a single constant-amplitude sine-wave audio tone into its audio input, the RF output is a single sine-wave RF carrier. If you shift the frequency of the single constant-amplitude sine-wave audio tone going into the transmitter, the RF output will shift in frequency only. So another way of generating an FSK RF signal is to generate an FSK audio signal and feed it into an SSB transmitter. At the receive end, the same principle can be used - the SSB receiver will convert the FSK RF to FSK audio.

If the SSB transmitter has sufficient unwanted-sideband and carrier rejection, the FSK signal so generated will be indistinguishable from one generated by a "true" FSK transmitter. The bandwidths, sidebands, and waveshapes will be exactly the same.

But Mr. Harrison claimed:

"SSB could be used to shrink this bandwidth."

That's simply not true. An FSK signal of a given bit rate and shift will have the same minimum required bandwidth regardless of how it is generated.

If one takes an FSK audio signal and feeds it into an AM transmitter, the result will be TWO FSK signals, one with inverted mark-space relationships, plus a carrier. The bandwidth required will be much greater, of course. The figure of 170 Hz for 100 wpm ASCII is for a single FSK signal, not a pair of them plus carrier.

My point was that there is no magic way to make an FSK signal narrower than the bandwidth required by the shift and bit rate.

Here are two formulas for bandwidth. These are the bandwidths necessary to send the signal without distortion. "bauds" in the following discussion is the number of code elements (mark or space) per second.

--

OOK (on off telegraphy): Bandwidth = bauds x keyshape factor

(keyshape factor is determined by the rise and fall times, and is typically 3 to 5. 3 is "soft" keying and 5 is "hard" keying.)

For Morse, speed in bauds = wpm/1.2

Example: 60 wpm OOK Morse (50 bauds) with keying softness of 3 has a necessary bandwidth of 150 Hz.

--
FSK (frequency shift telegraphy): Bandwidth = bauds + (shift x keying factor)

The keying factor is typically 1.2 for ASCII or Baudot

Example: 60 wpm FSK Baudot (45.45 bauds) with 170 Hz shift has a necessary bandwidth of 249.45 Hz (250 Hz)

--

Source: 1988 ARRL Handbook, Chapter 9. Checked against Reference Data for Radio Engineers.

You can make FSK many different ways, but you cannot make it narrower than the above formula predicts for a given shift and bauds.

>ours (ie, public property) so the government isn't *giving*
>anybody anything they don't already own.

The trouble is that the amount of the spectrum each of us can claim to "own" is extremely small. What is "earned" by getting the license is private access to public property. It's like getting a permit to have a party in the park. The park belongs to everybody, but everybody can't use it at once.

>We must all accept
>restrictions, for safety and to maximize use of this public
>property, just a we accept restrictions on which lane to drive
>in but there is no reason to "earn" what we already own. We
>accept driving tests to prove we can operate a car on public
>roads with reasonable safety, not to "earn" the right to drive.

The purpose of the tests for a driver's license are to show that one is qualified to use the public property (the roads).

>So I ask again, how can one justify requiring the people who own
>the spectrum to learn an archaic mode of communication (Morse)
>in order to use an entirely different mode (Voice).

Voice is older and therefore more "archaic" than Morse! ;-)

The main reason, acording to the FCC, is "We signed the treaty, and the treaty requires it". There are lots of other reasons, but that's the only one the FCC cares about any more.

>It might be
>reasonable to argue that some parts of the spectrum should be
>set aside for Morse on the basis of the numbers of people who'd
>benefit, and to require proficiency before using those bands,
>but the current and previous schemes are indefensable.

I and many others had to learn all sorts of stuff about modes and bands we've never used just to get access to HF bands where we could operate Morse. Why?

How about this: We should move away from the current structure of licensing in which more knowledge and skill gets you more spectrum, but not more modes or power (in general). For example, under the current scheme, a General class ham can use 3526 kHz but not 3524 kHz. How is the latter frequency substantially different than the former? It's in the Extra subband, that's all.

We should move TO a system of licenses-by-mode. Divide the bands up into subbands based on the mode used, and require testing of knowledge and skill in those areas. Morse, digital, analog phone/image would be the three most logical divisions. Each would have its own written and skills tests, along with a common "core" test on things everybody needs to know (safety and some of the regs).

Only problem is that the FCC wants simplicity.

: There is absolutely no need to use a balun at HF unless you are concerned
: about upsetting a directional pattern
: and of HF few antennas would be directional enough to care.

There are two ways that you can get currents on the outside of the coax,
even when feeding a balanced load. The first is leakage of current from
the inside of the coax shield to the outside. The second is coupling of
rf radiated by the antenna to the coax shield.

If you have rf currents on the outside of the coax, then the coax is
acting as part of the antenna system. This may, or may not, be desired.

Source record: 171304

Tim,
The CCD antenna is a good performer. It does have it's
'draw-backs'
though. It is long (full wave length), it's not the cheapest antenna
with all the mica capacitors needed, and it takes a fairly long time
to
build. It also needs a tuner to operate correctly. You will need as
many insulators as you have capacitors. Depending on the insulators,
dragging it over a tree limb may not be the easiest thing to do.
All that being said, I think it's a great antenna. If you make one
for the lowest band you use, it can be used on any band higher than
that,
and it works well. The 'shape' of the CCD antenna isn't too critical
at all. As long as you don't double it back on it's self, you can
zig-
zag it all over the place. It isn't height sensitive either. Of
course
it works better the higher you get it, but it will also work laying on
the
ground. It isn't an antenna you 'throw' up in a single afternoon, but
I
think it's well worth the trouble.
'Doc

Who said anything about shooting straight up? Furthermore, what person who happens to be a good enough shot to get the job done would stand directly below a big branch and shoot it off? Hmmm, perhaps, on second thought, if they were that careless to use the gun method they might also be stupid enough to stand under the branch.
I would not pretend to be at all expert about firearms, but I do know enough about them to have a healthy respect. Much depends on the specific firearm, the type and caliber of the ammo, and the amount of powder that propels it. If fired parallel to the earth's surface, the round will soon strike the ground (at a pretty high velocity). It would first travel many hundreds of yards. If the barrel is even slightly elevated, that round may travel for many miles before that happens. In fact, I believe it goes the farthest when fired at about 45 degrees. When it gets back near ground level it may have little more force than a tossed pebble (but not likely in most cases); it would likely have enough unspent velocity that it would easily kill humans and animals. I'm glad that you would not, personally, consider doing this. That's potentially one less sad story we'll see on the 6 o'clock news. So you physicists and ballistics experts out there check me on the minor details, but as far as I know, a bullet fired up in the air at an angle is extremely dangerous to others, and in other than a wartime scenario, anyone who would do that is either irresponsible or an idiot or both.
Just my 2 cents worth- YMMV (har)

Jim, N2EY wrote:
"An FSK signal of a given bit rate and shift will have the same minimum required bandwidth regardless of how it is generated."

Both AM and FM generate pairs of sidebands of equal amplitude and displacement around a central carrier frequency. Thus the sidebands on one side of the carrier frequency are redundant. They can be regenerated from our knowledge of the construction of the original signal which produces the single sideband, if such a reconstruction were necessary. Elimination of one of the spectra of sidebands before transmission reduces the bandwidth transmitted.

SSB may not be involved in any or all of today`s incredible modems. I haven`t checked into the tricks used for many years. The last time I looked, more and more amplitude levels were being encoded to shrink the transmitted bandwidth. But, already, modems were way beyond the bit speeds predicted as maxima by the classical theories. In many modems all maner of modulations were being combined to advance bit rates.

I meant to say that the electrical smoke signal had been vastly improved upon.

Best regards, Richard Harrison, KB5WZI

No but close.

But I guess if I used an electric motor to drive the differential it could be feasible.... but wouldn't the twisting moment on the shaft going up the tower be horendous (about 11m)?

HI
I have an SWB 2 don't know what the differences might be between the 2 & 3
but on the Swb 2 you just set the forward power on the left hand meter to
fullscale and read swr on the right hand meter it's quite simple.
hope this is of help.

Hi Bill:

You are correct, it is perhaps too broad a statement. I was referring to natural noise more so than man-made noise, which many times can be much more significant. The reason I chose not to reference man-made noise is that many times it can be a very localized problem, sometimes unique to an individual setup.

Thanks,

Pete,
I've used the 80 meter version and was dissapointed with it. It would put out a descent signal but I could not hear with it that well. I was using 100 watts at the time. Maybe it was because I had the antenna mounted about 10 feet off the roof of my townhouse at the time. I eventually gave it to a friend of mine who owned a townhouse. He installed it in his attic and also runs 100 watts. he was very dissapointed with it's performance and took it down. If you're runnung QRP from a camper I'd think you would be better off with a "Hamstick". Besides, they're less expensive than the Isotron or Bilal antenna.

True - but we're not talking about other radio services, we're talking about
ham radio, where Morse is widely used

>Hey, that's a _good_ use of CW, though.

One of many good uses.
>
>> >But, you miss the point -- you're not tested on

>> exam. Can an illiterate person get a ham license? I don't think so.
>
>Automatic CW 'modems' are also available

They are encoder/decoder, not modems.

> -- you can then copy CW by
>simply reading.

The encoder/decoder is doing the "copying", in that case.

>It just remains to make them more reliable due to
>poorly sent code. But, then again, poorly sent ASCII or Baudot would be
>the same.

Not just "poorly sent" code, but noise and interference.
>
>> >(knowledge of

>> >the mode works.
>
>> AND on ability to "copy" it.
>
>No one is tested on how to recognize RTTY by ear, now are they?

Nope - because RTTY isn't done that way.

> Is
>difficult SSB copy presented (phase shifting and other ionospheric
>artifiacts can make copy difficult)? Nope.

The Morse presented in the tests is not distorted or otherwise hard to copy. The test is similar to requiring someone to bang out two bars of "Chopsticks" or "Heart and Soul" on a piano before they can call themselves a musician.

>In fact, someone who is deaf is able to get a license -- the capability
>of copying SSB is definitely not tested then. Whether they are able to
>transmit SSB (and, using computerized voice recognition software,
>perhaps, they can receive it) is not limited, even if they can't copy
>it.

True - and blind people can use legally use SSTV.

>> >CW is outdated.
>
>> Why do you say that? Have you ever actually LISTENED to the HF ham bands?
>
>The Amateur HF bands are a small minority of 'the great majority of
>radio services' listed above.

HF is considered to be 3-30 MHz. Of those 27 MHz, US hams have access to 3.55 MHz - a little over 13%

>Sure, hams use CW -- but hams also use
>outdated FM equipment on 2 meters, too, that no one else can use.

Think about WHY they use it.

> The
>reason for amateurs' existence is spelled out in the rules -- which
>paragraph does CW Morse meet these days?

Well, let's see:

Morse permits more hams to use simple equipment they built themselves than would be possible if it did not exist. This promotes technical knowledge and development, which is one of the reasons for the ARS.

Morse helps bridge language barriers. I'm not saying it's a language in itself, but it does help eliminate the problems of accents and limited knowledge of foreign languages. Other modes do this too, but they are far less common and often out of the reach of developing countries.International good will.

Morse is widely used in traffic nets and other public service uses.

Morse helps build operating skills. Not just the ability to send and receive Morse, but how to listen, how to say things briefly, standard procedures, etc.
>
>Yes, I have listened to the amateur HF bands. Do you take me for a
>newbie?

I know how old you are but not how experienced. When I read anti-Morse statements like the ones in this thread I wonder how much HF ham radio the writers of them have actually experienced.
>
>> > Almost as outdated as spark.
>
>> Not at all. Do you know when spark disappeared from the ham bands, and why?
>
>The why is due to occupied bandwidth.

Not really. The why is due to the fact that for the same number of dollars spent, a "CW" (tube) transmitter would be heard much farther away, even if the power was much lower.

> The when was a very long time ago
>(around 1924).

Right. Hams abandoned it because tube rigs cost less for better results. It was outlawed for US hams in 1927 - long after nobody used it anymore.

It was outlawed for emergency maritime use in 1966.

> The then new 'CW' method of sending code was much more
>efficient, both in power and in occupied spectrum.

True - but "CW" wasn't new. It dated all the way back to 1906 or earlier. What changed was that tubes became cheaper, more reliable and more available. Plus things like Alexanderson alternators were not practical above LF.
>
>But you did know that I placed that clause in there as a troll, right?
>:-)

Sure.
>
>If persued on technical merits alone, CW would be dead now, due to modes
>such as PSK31 and MFSK16, which are more efficient and more capable than
>CW Morse (or Vail, if you want to go there) code.

That depends on how the "technical merits" are weighted. Are bicycles obsolete or outdated?
>
>But ham radio has never been only about technical merit.

Agreed!!
>
>> > -- protected subbands are good, though.
>
>> Agreed! In fact, how about this: Divide each HF band into 3 subbands, by
>mode:
>> Morse only, digital, analog voice/image. 35/15/50% is about right. To use
>the
>> Morse-only subbands, you have to pass a Morse test and a written test. All
>else
>> requires only a written test.
>
>I would go a little larger on the digital -- reference the recent PSK31
>interest.

The digital folks keep saying how spectrum efficient they are. If so, why do they need so much of the band?

>And with automatic CW 'modems' (such as the contest keyers
>many use), a test would really be superfluous -- but I wouldn't make it
>a sticky point.

If someone wants to use Morse, is a 5 or 10 wpm test any sort of problem? I don't think so.

>30-20-50, maybe?

There's a lot more Morse than digital on the HF ham bands.

>Or 33-33-34, even?

That would mean less room for 'phone than there is now.
>
>> Something for everybody.
>
>Right -- something for everybody. No one forced to learn a mode they
>won't use. Exactly my point.

Then how do you justify forcing me to learn about SSB, and FM and TV and VHF/UHF and lots of other stuff when all I wanted to do was work Morse on 40 meters? You shoulda seen the old writtens.

Gary,
The ATAS 100 covers 40mtrs-70cm. I have used one mobile and found it to be a great antenna for what it is. It will tune by itself with no tuner with the FT 847 and the FT 100. There is a Ground Plane or counterpoise kit for it for just such a situation as yours. If you do decide to go this route I would string some extra counterpoises in the attic. the average screwdriver is over 10ft long fully extended and the ATAS is only 59 inches extended (excellent for a tight attic).
73 and best of luck

Re-tune all the wires starting with the longest (20m) and working back to
the shortest (10m)
You are getting interaction that must be tuned out.
Hang in there as it is a long process but your antenna will tune and work
like it should with no tuner required on any of the bands.

No one is tested on how to copy RTTY by ear, now are they?

N2EY replied: "Nope - because RTTY isn`t done that way."

How ironic! Sam Morse aimed to develop a machine to receive his code. When machines were developed such as Telex and Teletype, many of the amateur manual operators, just like John Henry, "The Steel Drivin` Man" insisted on clinging to their manual methods.

The hobby is "amateur radio", not "amateur Morse".

Morse is no longer needed to practice radio and hasn`t been since the invention of the continuously variable modulator.

Morse is an archaic relic. It is not needed to enjoy radio, and Morse is not used professionally in radio. Testing for Morse ability is inane.

Best regards, Richard Harrison, KB5WZI

Hi Pat -

I haven't been there for a year or so; but the last time
I was there, the retail showroom had been closed down.
They did have a smallish-looking parts counter, and
component distribution business, still operating in the
old building.

Those are degree graduation requirements, not prerequisites
for *entrance* into college. Too many hams consider their
license to be some sort of graduation certificate when it
is merely a ticket to gain *entrance* into ham radio.

It's an ASK modem, actually. Codec/modem -- same effect. Just the
keying method is different -- FSK, PSK, or ASK. High-speed
trellis-coded QPSK modems use ASK as well as PSK.

> > -- you can then copy CW by
> >simply reading.
> The encoder/decoder is doing the "copying", in that case.

Not really. You are copying the text, just like you are copying RTTY
after the modem.

> >The Amateur HF bands are a small minority of 'the great majority of

> Morse permits more hams to use simple equipment they built themselves than
> would be possible if it did not exist. This promotes technical knowledge and
> development, which is one of the reasons for the ARS.

AM DSB-FC is simpler for the receiver. The transmitter for AM
double-sideband full carrier is almost as simple as a CW transmitter --
especially with plate modulation in a transformerless setup (high
voltage carbon mics can even be used -- been there, done that).

Of course, AM DSB-FC has other problems CW doesn't have. CW actually is
ASK (Amplitude Shift Keying), if you look at it closely.

And there is a sort of AM revival occuring, with surplus broadcast band
transmitters showing up in top band.

> Morse helps bridge language barriers. I'm not saying it's a language in itself,

> often out of the reach of developing countries.International good will.

Any digital code can do the same -- Morse is not unique in this regard.

> Morse is widely used in traffic nets and other public service uses.

Only on the ham bands. The ARS also exists to train communicators in
case they are needed on other bands and in other services, where Morse
is gone.

> Morse helps build operating skills. Not just the ability to send and receive
> Morse, but how to listen, how to say things briefly, standard procedures, etc.

There are more ways to build all these things than just Morse.

> >Yes, I have listened to the amateur HF bands. Do you take me for a

I am experienced enough, listening-wise. Not all those who have CW
experience grow to like or enjoy the mode.

> >> > Almost as outdated as spark.

> >The why is due to occupied bandwidth.

> Not really. The why is due to the fact that for the same number of dollars
> spent, a "CW" (tube) transmitter would be heard much farther away, even if the
> power was much lower.

Because occupied bandwidth was smaller, the power density was higher,
even with lower total power.

> That depends on how the "technical merits" are weighted. Are
> bicycles obsolete or outdated?

High-wheelers are obsolete. Mountain bikes are a fun hobby -- but you
don't use them on the freeway. And, in fact, bicycling is illegal on
some roads, for safety.

> The digital folks keep saying how spectrum efficient they are. If so, why do
> they need so much of the band?

The same can be said of CW.

> If someone wants to use Morse, is a 5 or 10 wpm test any sort of problem? I

The B.F.A. degree is a credential that you`ve satisfied more than the vocational knowledge needed to paint, play an instrument, or whatever. It is not a license to practice anything. Enjoy your degree for the aggrandizement it gives.

Licenses are typically issued to deny access of inept non-license-holders to positions where their practice may likely result in the death or serious injury of someone. Licenses are usually issued on demonstration of knowledge and skills needed to avoid mishaps. A fishing license is an exception. It only shows you`ve paid a fee. Ham licenses could logically be in the same category as fishing licenses.

Radio has progressed to the point of popular familiarity. Safety of life no longer requires such tight regulation as in the early days. The captain and flight attendents will tell you if and when it is safe to use your electronic devices. Tight licensing requirements are counterproductive.

The FCC found itself in the position of issuing credetials (the commercial operator license) mainly for the benefit of the employers of radio technicians. It was evidence of some knowledge and skill. It wasn`t really needed to protect safety. So, they`ve mostly discontinued the practice.

The FCC has heard all the arguments made about ham licensing when they were eliminating most commercial licensing. They now have the experience of commercial deregulation, and it wasn`t dire at all.

Overall, I think a waste of capacitors and time needed to solder all the
connections. I've worked quite a few over the years that used these, and
although most seemed to like them, I never could really see why. They
sure didn't seem to radiate any better than a regular dipole. Maybe
worse...To each his own I guess...Myself, I wouldn't bother with all
that work. MK

If you are talking about conventional voice modulation, yes.

> Thus the sidebands on
> one side of the carrier frequency are redundant.

In AM, this is true. In fact, in AM the carrier isn't really needed,
either. And there's just one pair of sidebands unless the signal is
overmodulated.

In FM, the story is quite different. Depending on the modulation index,
the carrier may completely disappear. There are several pairs of
sidebands, not just one pair, and the energy in them depends on a bunch
of factors.

You cannot just run an FM or FSK signal through a filter and lop off
half the sidebands and wind up with a usable, nondistorted signal like
you can with AM.

In FSK as typically used for ham radio, there is no "center frequency".
Instead, there are mark and space frequencies, and the carrier wiggles
back and forth between them. The necessary bandwidth is as given in my
earlier posts.

> They can be regenerated
> from our knowledge of the construction of the original signal which
> produces the single sideband, if such a reconstruction were necessary.
> Elimination of one of the spectra of sidebands before transmission
> reduces the bandwidth transmitted.

On AM, yes. Not on FM. FSK is just a form of FM.
>
> SSB may not be involved in any or all of today`s incredible modems. I
> haven`t checked into the tricks used for many years. The last time I
> looked, more and more amplitude levels were being encoded to shrink
the
> transmitted bandwidth.

Modern modems use multiple carriers, phase shift keying, and some ofher tricks. For "landwire" use, they work because the telecom companies pay attention to things like not having phase distortion or selective fading. The modem design is tailored to the known qualities of the telephone lines.

And even with the tricks, many lines that are perfectly fine for voice comms are useless for 56K modems. Some even fail at 28.8k

> But, already, modems were way beyond the bit
> speeds predicted as maxima by the classical theories.

Nope. The theories are correct. The modems do not violate them.

> In many modems all
> maner of modulations were being combined to advance bit rates.

Exactly! And the virtues of the classical modulations are sacrificed. For example, FM is highly immune to impulse noise. Using a combination of AM and FM gives a higher speed than FM alone, at the price of much lower noise immunity.

What works on phone lines will not necessarily work on the air. If PSK is so good, why isn't it used for moonbounce?
>
> I meant to say that the electrical smoke signal had been vastly improved

> 73, Bill W7TI

Hummmm, I'm in a urban area here. "Houston". I've never had any real
problems with noise when using verticals.
If I get noise on a vertical, I usually will on the dipoles also. I
notice that the dreaded "power line noise" doesn't really seem to favor
one over the other. It usually nails both. I've seen many cases where
the noise floor would be higher on my 40m GP than on the dipole at the
same height, but the desired signals would be higher also. So it didn't
matter. Say if I work 1500 miles away. Dipole shows S3 noise, maybe the
GP might show S4. Did it matter? Heck no...The GP would receive the
desired signal 2 s units louder than the dipole would. So if the signal
using the dipole was S7 or 4 s units over the noise, the GP would be S9
or 5 s units over the GP's S 4 noise. Even with the apparent higher
noise level, I'd still rather be on the GP for that distance any day
over the dipole. These numbers used are pretty much actual results to CA
from Houston on 40m at night. Many times I found the GP to actually be
pretty darned quiet under good local cdx. MK

His original machines made a wavy line on a strip of paper. Human operators translated the wavy line into letters and numbers. He never built a working printing telegraph.

Optical telegraphs existed long before Morse - he perfected the electrical telegraph.

> When machines were developed such as Telex and Teletype, many of the
> amateur manual operators, just like John Henry, "The Steel Drivin`
Man"
> insisted on clinging to their manual methods.

You ever drive steel? I have. Rail spikes, too. Machines cannot do it all.

When steamboats were developed, many boaters "insisted on clinging" to sail. Bicycles are still used extensively, despite the fact that motorcycles and cars have existed for almost a century. Some people even play their own music, sew their own clothes and cook their own food, despite techncially excellent and inexpensive alternatives.

Some of us even design and build our own ham gear.

There is value in simplicity, in doing for oneself, and in developing skills even if they have no "professional" use (meaning one doesn't get paid for them). There is value in doing a thing well for its own sake.
>

> invention of the continuously variable modulator.

Agreed. Knowledge of how a radio works isn't needed, either, and hasn't been since the development of manufactured receivers and transmitters.
>
> Morse is an archaic relic.

Why do you disparage the mode so? Would you say that to a cyclist or the sailboater?

> It is not needed to enjoy radio,

But many find it enjoyable in radio.

> and Morse is not used professionally in radio.

Yes, it is. The use is very limited, but it is still used in some applications.

But why does what the "professionals" do matter to us "amateurs"? The "professional" aviation folks have all but given up on piston-engine airplanes - does that mean amateur pilots must stop enjoying them?

The "professionals" have abandoned the whole idea of "radio operator", too. Does that mean "amateur radio operators" should no longer exist, either? I hope not.

> Testing for Morse ability is inane.

Whoa - who is talking about TESTING?

I keep trying to explain this, but folks just don't seem to get it. The whole testing thing is a dead duck - a moot point - a done deal. FCC has already reduced Morse testing to the bare minimum possible under the treaty, and won't reduce/eliminate further until the treaty goes. What you or I think or say about testing Morse doesn't matter - the FCC won't eliminate it with S25.5 as it is now, and they sure as heck won't increase it. They reduced it as much as possible to eliminate as much of their own admin work as they could, despite all sorts of arguments and recommendations by a majority of interested parties. Democracy counts for very little with them on this issue. It's clear that they will dump Morse testing as soon as the treaty changes, but not before.

All modes have their good and bad points. But from what I read here and a few other places it's clear that some folks aren't satisfied with the end of Morse testing - they want the end of Morse USE. They want to tell us Morse ops what we should like, and why. Well, just call me Edgar Friendly, or Number Six, because I like to pound the brass, copy the signal myself, and be a radio operator. Even if that makes me "obsolete".

Be well.

2167. Beware of defective RG-213 from Radio Works

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-30 18:12:22 UTC
From: Floyd Sense <sentek@sprintmail.com>
Message-ID: <auDd6.213$QI5.18117@newsread2.prod.itd.earthlink.net>
Source record: 171240
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment

Just wanted to warn everyone about some bad coax being distributed by Radio Works. The cable in question is their "RG-213 Plus", and according to their catalog "features an improved braid and even better quality, non-contaminating jacket". When I notified them of the defects in the original cable shipment, they promptly shipped out a replacement length and issued a UPS pickup for the original cable. After foolishly installing connectors on the new cable, I inspected a few feet of it and found it to possess the same defects as the first batch. If you've purchased any of this stuff recently, I suggest you look it over carefully before using it. The info printed on the cable jacket is: "IEWL 4062 213/u Type"

Here's what I found in my cable:

1. While paying out the cable, I encountered a roughness in the outer jacket that felt as if the cable had been scraped. A closer inspection revealed a poorly closed seam running the length of the cable, where the jacket ends had been fused together. The rough spots, in places, were actually small rough holes. One of the holes was large enough I could actually see the copper braid.

2. In a couple of places, there was a "lump" in the cable, up to an inch or so in length. I've opened up such cable sections in the past to find that the braid had been folded back over itself at that point. Usually, braid damage accompanies such a defect (torn strands, etc.).

In addition, while soldering on the connectors I noted that one of the braid sections (multiple strands of wire) was considerably oxidized. Hard to believe that the manufacturer would go ahead and make cable with such material. The oxidized section was not present in the first cable shipment I received.

2169. Re: What is a half wavelength vertical?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-30 18:55:01 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3A770E05.3854A1D9@eznec.com>
Source record: 171245

Can you explain why "40% of the power is burned up in ground losses due to lack of radials" with a half wave vertical? This isn't consistent with either the theory I'm familiar with or the results shown by modeling programs.

Here's what I see as equalizing the quarter and half wave verticals: The half wave vertical would have a 1.6 dB gain over a quarter wave vertical if both were over perfect ground. The gain is accomplished by concentrating the signal at the horizon. Over perfect ground, the half wave's pattern is narrower, with a higher proportion of the energy at low angles. But except for salt water, real ground bears very little resemblance to perfect ground. And when a vertically polarized signal reflects from real dirt ground at low angles, most of the power is dissipated as heat. The result is that the low angle radiation disappears. But the half wave vertical concentrates a higher proportion of its total field at these very angles, so a higher proportion of the total radiated power is lost. This tends to equalize the antennas. On the other hand, the quarter wavelength antenna will usually have lower efficiency due to ground loss resistance, giving the half wave antenna an edge in this regard. Both these factors depend on the ground conductivity, so either antenna might be very slightly better than the other in an individual installation. But if the quarter wave antenna has a decent ground system, you're not likely to see a spectacular difference.

Roy Lewallen, W7EL

2170. UHF Bowtie - DIY?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-30 19:00:38 UTC
From: Jim Lill <jpl@vectorbd.com>
Message-ID: <95730g$ht0$1@nnrp1.deja.com>
Source record: 171244

I live very close to the local TV xmitters. I'd like to use a simple bowtie dipole to cover 21-59. I cannot find the info on how to get the angle correct. I'm pretty sure that you can get darn close to 300 ohm Z feed and that can connect to a simple balun/coax etc. I would have thought that the angle would be a snap to find, NOT! Obviously the length is non-critical by comparison.

TIA

-Jim

Back in '58 or '59, I built a little 5 watt AM transmitter for 6 meters, according to Mister Orr's
instructions. I also modified an ARC-5 receiver for home use, according to an article he wrote. He
will be missed.

The news is on the arrl webiste, http://www.arrl.org I don't often visit
that site, but I was wanting to know the price of "200 meters and Down"
yesterday, and checked the news while I was there. His death was last
week, I think the 24th. I was a little surprise that I didn't read
it in the newsgroups first, because that is how I've heard of the passing
of various important hams over the past few years.

I got a 19th edition of Bill's Radio Handbook for Christmas in 1972,
me being 13 years old and licensed for six months. I had an ARRL
Handbook at the time, but I didn't have many books about electronics
or radio. Somehow having a hardcover handbook was a big event. ALmost
thirty years later, that edition beats out the other two I've bought
since. And while I used and abused it as a kid, it's still in pretty
good shape.

Jim, WA2ZKD wrote:
"I`d like to use a simple bowtie dipole to cover 21-59.

Well the bowtie is a type of biconical antenna. Arnold B. Bailey has these in "TV and Other Receiving Antennas".

He makes each side of his conical dipole from (6) 22-inch long 1/4-inch dia. rods.

Separation of the apexes is 2 inches.

They are fanned out to an angle of 60 degrees.

Bandwidth is about 200%.

Design frequency is 200 MHz. For 600 MHz, use rods about 7 inches long.

The 200 MHz rods are flared into a circle about 23 inches in diameter, so that the structure of a side projects almost as an equilateral triangle.

This is a "full-wave" dipole. 1/2-wave dipoles of similar design work but have just a fraction of the bandwidth.

104-ohm balanced transmission line is recommended. You can probably get away with other more available feedlines.

Best regards, Richard Harrison, KB5WZI

2175. Modelling High Frequency Antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-30 23:02:25 UTC
From: Paul C Elliott <pc.elliott@btinternet.com>
Message-ID: <kqMK9gABg0d6Ew+U@btinternet.com>

Is it possible (sensible) to model microwave horns, dishes etc. using
NEC based programs. I know NEC has a surface patch facility but its only
available in the more expensive commercial packages, or the original
text only version and is it useful for this type of application anyway.
I've tried wire frame models with limited success.
Is there a limit to the MOM type techniques at higher frequencies
perhaps giving way to ray type analyses?
Has anyone any suggestions for software to use in this area.

Regards,
Paul

Paul Elliott (G0TXL) Email g0txl@btinternet.com

2176. Re: Modelling High Frequency Antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-30 23:50:45 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3A775355.515C66EE@eznec.com>
Source record: 171250

NEC patches are useful only for enclosed objects like boxes, and not for such things as horns or dishes. The reason is that the current on an unconnected patch edge is forced to zero, while on a real conductive plate the current flows over the edge. Wire grid models do a better job of imitating flat surfaces, but they also have their shortcomings. They're not as opaque to fields as a real metal plate would be, and they can be tedious to construct. People modeling dishes are frequently interested in sidelobe levels, which can be sensitive to surface shape and roughness. It wouldn't be practical to create a wire grid which is adequately exact in shape to give an accurate result for such things as sidelobes. So all in all, I don't think NEC based programs are very useful for these kinds of antenna structures.

There's no frequency limit to NEC programs or any other MOM programs I know of. Frequency is simply a scaling factor.

I wrote:
"104-ohm balanced transmission line is recommended."

I should have pointed out that two 50-ohm coax lines can be used to connect the conical dipole. Connect to the conical dipole using only the center conductors of the two coaxes. The two shields can be joined together. A good match should be obtained at the resonant frequency of the antenna.

Best regards, Richard Harrison, KB5WZI

I don't think the differential bought much gear reduction.
I wonder if an old automobile gearbox would give appropriate reduction with one of the gears? Hmmm... must be a better way.

It's easily the best low cost active antenna available. The AN-LP1 includes a unique folding loop antenna, a case with battery compartment, preselector and long crank wind leads (one for the radio and one for the antenna loop) as well as assorted gadgets such as a filter and hardware for connection to a wide variety of receivers. I use my AN-LP1 with a Sony portable (SW55) so it just plugs into the antenna jack. Read the reviews of this antenna in Passport to Worldband Radio. BTW the 2001 edition contains reviews of all the active antennas worth considering.

Another poster (whose name I forget) made the statement about 40% of the power is
burned up. I completely agree with you; I think we are trying to say the same thing.
The half wave vertical's pattern gain makes up (approximately) for ground losses away
from the base, so in practice, a half wave with no ground radials is as good as a quarter
wave with a lot of radials. I found that adding radials 4 wavelengths long to the half
wave vertical allows it to realize the ~2 dB gain over the quarter wave. This study
has been posted on my web site www.karlquist.com for several years. The bottom
line is build whichever is easier for you as the performance is about the same.

The whole testing thing is a dead duck - a moot point - a done deal. The FCC has already reduced Morse testing to the bare minimum possible under the treaty,---."

Moot means arguable or doubtful. This thread has confirmed that code/nocode is "moot".

Why do I think the treaty story is just another story to postpone the inevitable? Because it fits so well with all the tooth and nail resistance to change the hardheads have demonstrated for half a century.

I`m not familiar with the international agreement which is supposed to prevent further relaxation of Morse testing. I expect it`s been grossly misrepresented to mislead the gullible. Many treaties direct conduct with no provisions of penalties for treaty violations. It must be that way when there is no mechanism for enforcement. It is that way for European poultry production and nuclear test bans. A lot of countries including the U.S.A. stick to a treaty as long as it seems to serve their interests and then freely deviate when the perceived interest is for violation.

I`d wager there is no need for the U.S.A. to require a 5 WPM code test by any international agreement. There may be an agreement for some very unspecific testing for code operators on some parts of the radio spectrum. But, they are probably without meaning, penalty, or method of enforcement.

The U.S. could today say no more code tests from this day on in this country and nothing could or would be done about it anywhere.

Best regards, Richard Harrison, KB5WZI

I know this may sound funny, but does anyone out there know how trees grow? If i leave an antenna wire up in a big spruce tree (over a horizontal branch) at 100 feet up, in five years or so will it be at 105 feet or any higher at all? I know that these trees grow in girth at their bases, but do they "telescope upwards" or do they just grow vertically from the top? Many thanks for any informed responses. 73, de John, K7JY, Seattle.

No, the horizontal branch's center will always be at the same elevation.
The branch will increase in diameter above and below.

There is a survey blaze mark made on a tree on my farm perhaps 100 years ago. Though the tree got much taller, the mark remained at nominally the same height.

Trees grow taller mainly by extending at the very top.

John,

That is an interesting question. As far as I know trees grow from the top and in the lower parts they get thicker and thicker. Look for example how a plant grows. Of course it depends on the age of the tree. Branches can change shape and direction. The leaves grow towards the light. That's also how the branch chooses it's growing direction.

That's all I can say about it. Maybe you should place your question in a newsgroup for biological subjects as well or check the library for books about this subject.

How high is it? I forgot...Seems yours was too low for 8 radials to work well wasn't it? Like 10 ft or so? Mine was 36 ft high at the base with 4 sloping radials. Same height as my test dipole. How does the height of your test dipole compare with your vertical? I've got a funny feeling it's higher. MK

It'll stay at the same height. But the branch and/or trunk will grow around your wire, so before long you won't be able to get it back down. Trees grow from the top, and they also increase diameter. They don't grow from the bottom and push things up. Too bad -- the sequoia in my back yard was 8 feet tall when I moved here, and it's around 70 feet now. Every few years I have to climb it if I want to take advantage of its increasing height. (I put a pulley on a long screw eye. Eventually the tree grows over the screw eye as its diameter increases. I don't shoot a wire or rope over the top, since I want to be able to get it back down for modification or to try different antennas.)

I'd probably do it like in the old days. Just make the loop and hook directly to the tv ant terminals. The size etc not all that critical. You could use stiff wire and hook each end to the 300 ohm uhf terminals and form a loop about 5-6 inches dia and would work ok I think. About a foot or so of wire should be plenty. You probably can still buy these antennas ready to go. Maybe at radio shack. They would be better as they swivel and can be turned. MK

My dipole is 40ft high and is a full-wave on 40m. My 33ft 40m vertical
is ground mounted with 8 buried radials. However, I have never seen
the vertical beat the dipole even off the ends of the dipole. :-(

The U.S. could today say no more code tests from this day on in this country and nothing could or would be done about it anywhere.

Best regards, Richard Harrison, KB5WZI

But that is not the way things are done in a civilized, rule based society. The rules are in place. Whether you are familiar with the treaty or not, is not relevant. Whether the rules could be ignored without consequence is also not relevant. The treaty will no doubt be modified and many expect fully that the CW requirement will go away completely. Until the treaty is modified; however, it is not very responsible of you to be advocating disregard for it.

You don't seem to grasp the fact that you have won the battle Richard. Are you so filled with anger about the past CW requirements that it is blinding you to current reality? Take advantage of the new rules Richard; there is no more 20 wpm requirement; nor 12 wpm; go get your Extra. No need to hang around at Tech Plus. With the technical knowledge that you like to lay on us daily, all you have to do is ask for the Extra and it is yours! You have won! Pull yourself out of this bitter; angry mood related to CW and all of us old time hams that did it our way. You can now do it your way! Go for it!

Sure , not ground mounted with only 8 radials. I tried the same thing at first, but with 32 radials. Mine "ground mounted" didn't beat my dipole either. But my elevated one sure did. Bigtime. My GP at 36 ft with 4 radials was about equal to a ground mount with 60 radials. Quite a difference between 8 and 60. Even with 32 radials I wasn't impressed with the ground mount. But elevating a 1/4 wl was like turning on a switch.Try your antenna at 35-40 ft and see what happens. I bet you change your tune. :) My GP never lost to the dipole over 1500 miles away. Not even once that I can think of. If I was working CA. and switched from my GP to the dipole, it was like reducing my power from 1000w to 100w to them. Of course, when I used that antenna I did run a full KW usually, so I tended to brown the food over there most nights. The combo of the GP and a KW was a killer on 40m late at night. I'd be over S 9+ usually overseas. Unless I switched to the dipole that is. Then I'd drop to S 6-7 or something like that. From the USA to dx, only the guys with directional arrays "IE bobtail curtains, etc" or yagis could beat me. One of these days I'm going to phase two of them. That oughta be a hoot. :/ MK

Murray I have been thinking about what you said regarding the
differential and also note what you said below

Perhaps the gearbox and shaft drive off a motorcycle would be the order
of the day.... I haven't investigated this but I see no reason why it
couldnt work after all if those gearboxes can handle 75+hp they should
handle an antenna, their compact size has to be a plus too.

Your antenna will still be 100 feet high, the tree top will be about 20 feet taller however.

I did this with an old windscreen wiper motor.

I had a bearing in the roof pitch and dropped
the aerial pole into the roof so I could run
things in the dry.

The motor already has a big step down so it
drove a little pulley with a big pulley on
the bottom of the pole made out of three bits
of chipboard bolted together.

It was gloriously Heath Robinson but worked
a dream for five years till I moved.

I had a 360 degree pot (I've not seen them
recently) driving a panel meter calibrated
in NSEW.

Your argument makes a bit more sense than some of the others, Richard!
However there are Many licenses that only require a fee to be paid and I
don't think that matters one hoot.
I and many of my ham buddies do not like or use code.
But we wanted to be hams so we learned it because it was a requirement.
Just like some of those stupid, useless, courses I took to get a diploma.
It was not easy.
It required a lot of WORK and EFFORT on my part to achieve.
I was willing to put forth the effort because I wanted it and felt it was
worth the effort.
Now all one needs to do is learn 5wpm.
Is Ham radio not worth even that effort anymore?

But Mark .... most all who use a vertical antenna mount it at or close to groung level or on the bumper of their car. City dwellers dont have a lot of room to string out wire dipoles. That is why most of them choose a vertical to start with. Not everyone can install a 40m GP at a heigth of 36 feet. it requires to much real estate and support structure to fit a city lot.

Change the pre-amp on the mast to a narow banded one which has decent band pass filtering. It sounds as if you are overloading the distribution amplifier which in turn is giving the TV's grief.

Where on the internet could I find out information on the different characteristics of antenna wavelengths? I am looking to install a mobile 2M antenna and am trying to figure out what style of antenna to get. From the little I've gathered a 1/4 wave needs a great ground plane has little gain but its pattern is more vertical which might help out traveling in valleys. 5/8 has a higher gain buts its pattern is more horizontal. 1/2 does not need a ground plane. I would really like to understand this a little better.

THANKS

2212. 40 meters mobile noise

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-31 17:23:01 UTC
From: wehowell@aol.com
Message-ID: <20010131122301.10361.00000020@ng-cu1.aol.com>
Source record: 171186

I have a '90 Ford Ranger pickup that I mant to operate with a mobile rig on 40/20 meters (ICOM 706 MKII with auto tuner), however, the RFI is too great. The chief offender is the fuel pump which is buried in the plastic fuel tank. Has anyone had any experience with this. To bypass the fuel pump power line to ground (anywhere close to the exit point) will require that I drop the fuel tank. I am not ready to do that unless I have some indication that it would improve the situation.

All information I have is that Ford does not have a TSB on the subject.

I have tried nominal fixes such as rerouting the antenna cable; this has some effect but not significant. The antenna is mounted on the driver's side rear.

With the feed line diconnected at the antenna the noise is slightly reduced; disconnected at the output of the antenna tuner the noise is completely gone - so the noise is getting in through the feed and antenna.

Thanks for any suggestions

Grasses grow from the bottom and telescope up.
That is why you can mow your lawn and have it keep growing. Grass evolved to survive being eaten by grazing animals. Corn is the largest grass I am familiar with.

I disagree - modems are not encoder/decoders, they're
modulator/demodulators. A ham rig is a form of "RF modem". But let's
not play word games - whatever we call 'em, there are devices that will
turn received Morse into text and vice versa.

> interests, due to regulations, cannot use it.

The most important reason hams use analog FM on VHF/UHF is that nobody has come up with and SOLD an alternative that does the same or better job for hams. (By "SOLD" I mean "publicized and promoted to the amateur population").
>

>
> AM DSB-FC is simpler for the receiver.

Not for HF.

The simplest practical amateur HF/MF receiver is a regenerative detector/audio amp design. Such a receiver is usable for Morse, AM and even SSB (if carefully built) with no additional equipment.

Another simple design is the direct-conversion receiver, which overcomes many of the regenerative's shortcomings. Direct conversion sets are actually BETTER for Morse and SSB than they are for AM.

> The transmitter for AM
> double-sideband full carrier is almost as simple as a CW transmitter --
> especially with plate modulation in a transformerless setup (high
> voltage carbon mics can even be used -- been there, done that).

Do you think such a design is really practical today? I don't.

On the other hand, many thousands of hams are on the air using simple Morse HF gear and working the world with it. It is a "first step" that is a big benefit of the mode.
>
> Of course, AM DSB-FC has other problems CW doesn't have.

Yup. The ~17 dB S/N disadvantage of AM is one.

> CW actually is
> ASK (Amplitude Shift Keying), if you look at it closely.

Of course. OOK is just AM taken to the limit. FSK is FM taken to the limit.
>
> And there is a sort of AM revival occuring, with surplus broadcast band

> transmitters showing up in top band.

Been going on for over a decade - and it's not just old BC transmitters or 160 meters. Old AM rigs that used to be considered "junk" are now highly prized and sought after.

As I wrote: "Other modes do this too, but they are far less common and often out of the reach of developing countries."
>
> > Morse is widely used in traffic nets and other public service uses.
>
> Only on the ham bands.

That's what matters. We're talking about ham radio, not some other service.

> The ARS also exists to train communicators in
> case they are needed on other bands and in other services, where Morse
> is gone.

Yup - but how many communicators do those services need anymore? It's not just the code which is gone from other services, it's the whole idea of a "radio operator" that they are trying to phase out. The shipping outfits like Exxon and Zapata pushed for the end of mandatory maritime Morse because they wanted to get rid of the OPERATOR.
>
> > Morse helps build operating skills. Not just the ability to send and receive
> > Morse, but how to listen, how to say things briefly, standard procedures, etc.
>
> There are more ways to build all these things than just Morse.

Of course! But the question was about which of the Part 97 bases and purposes Morse supports. The existence of alternatives does not diminish the importance and contribution of Morse to the ARS.
>

Exactly. And there are bike paths and lanes where motor vehicles are
banned.

In other words, the emergence of new technology did NOT "obsolete" the
old technology.
>

> > The digital folks keep saying how spectrum efficient they are. If
so, why do

The concept of "why do I have to learn this if I'm not interested in
using it?" is exactly the same. That's the important point.

> But, it's a moot point.

Yup. FCC has spoken, and it's very doubtful their direction will be
changed.

This has always been a problem with late-model Fords. I've heard numerous people say replacing the pump does nothing to help the problem. About all you can do is ground, ground and ground some more to try to minimize it. That, or rip out the OEM pump and put in a different one in-line.

The fuel pump is a likely candidate. You can hear that noise when you first turn the ignition key to the on (NOT start) position. The pump will run for two seconds.

Ford has some tech notes on killing the pump noise but it really is only partly effective. I suspect it could be very expensive on an out-of-warranty vehicle. The pump on my old '94 was inside the tank.

You'll find a very good article on "Ford Noise Problems Revisited" on page 6 of the Feb, 2001 Worldradio magazine.

Good luck... Ed, W5EJ

2220. Weird RFI

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-31 19:12:33 UTC
From: Pete Holden <peholden@home.com>
Message-ID: <BsZd6.140017$ge4.51323780@news2.rdc2.tx.home.com>
Source record: 171193

I have an Icom IC756. The spectrum scope shows the activity on the band across selectable ranges from 25 kHz to 200 kHz.

Sometimes I will get static that shows up as a sawtooth pattern lasting for several seconds, then disappearing and reappearing. In fact, if I quickly jump to another ham band, the sawtooth will be there also.

Now here's the weird part. Presumably each tooth on the "saw" represents a transmitted frequency. But, if I quickly change the scope's range, the "teeth" don't get close together or farther apart. So, when the range is 25 kHz the teeth appear to be about 1 kHz apart. But when the range is 200 kHz the teeth seem to be maybe 7 kHz apart.

Any ideas?

Thanks, Pete KATZK

I hope they receive a whole lot better than the one I bought 10
years ago. It worked perfectly on machine-generated Morse but
very poorly in actual practice. I'd hoped to use it to "back up"
my own skills and thus improve them but found I spent more time
trying to figure out the garbage it was displaying than trying
to copy code myself so I quit using it. I suspect that most hams
have much poorer fists than they'd like to admit; that a good
ear and skilled mind can gloss over their mistakes but older
machines like mine cannot. How about the new PC sound-card SW??

Possibly the Rx scans relatively slowly and there is some form of
storage in the system. So the same interference appears on two bands and
also the 'size' stays the same.

Hi Pete,

You have sampling (Nyquist) error that is causing the spectrum to
fold. The first indication is in your description of "saw" shaped
products (perhaps for a time based measure, but not a frequency based
one). You need to slow the sweep speed and reduce the frequency
spread that is being swept for an accurate representation.

Jim N2EY wrote:
" - modems are not encoder / decoders, they are modulators / demodulators."

Then, there is the "null modem", and there is the "codec" which codes and decodes.

Jim also wrote:
"Reading is not the same thing as copying."

How about "Fax" or "Xerox"? Or, how about:
"Hello London? Do you copy? How do you read me?'

Saw a PBS broadcast last night about the "Star Dust" a British passenger plane that crashed in the Andes between Mendoza, Argentina and Santiago, Chile in 1947. I`ve flown that route a few times so I watched.

The plane reappeared after being hidden in the snow for about 50 years. The glacier finally moved low enough, carrying the wreckage with it, to expose the wreckage.

Evidence now is that the plane was flying above the overcast which completely covered the mountains. (Been there, done that, and can say it is hard to keep your cigarette lit above 20,000 feet when the cabin isn`t pressurized, and you sure feel compelled to smoke if you are addicted in that situation.) The pilot found no "hueco" (hole) in the overcast, it seems, but he had been flying so long that he must have been sure that he had cleared the moutains and was dscending to Santiago. He had no way of knowing that he had been facing a headwind of about 100 MPH. He crashed in the fog on the Argentine side of the Andes.

He only had CW contact, and shortly before the crash he made only one transmission. In Morse he sent "STENDEC", repeated 3 times. That combined with complete disappearance of the plane lead to speculation of an "alien abduction". Nobody it seems has a clue as to what that transmission might mean. They have tried recomposing the dits and dahs to see if other letters might make more sense. The operator was English and is supposed to have been using the English language. I don`t have a clue.

More about the story is posted on the PBS website.

Best regards, Richard Harrison, KB5WZI

You guys underestimate what being 1/4 miles from 7 TV stations is like!!
Anything new the set will have severe reflections. I want a nicely
matched, low Q, Broadband solution that I can put up in my all-wood
attic and feed with coax.

The bowtie I mentioned would be a spin on the type RatShack sells that
have reflectors, just an essentially 2 flat pieces of metal, I'll skip
the reflector screen.

I have something I guessed the angle at, and it works pretty well. I
made it using "sticky copper tape", EMI/EMC shielding stuff, putting it
on a sheet of lexan.

I'd like to get the angle right then play with the feed-Z and line.

Is there a rule of thumb for how far to keep ladder-line conductors away from other conductors?

I need to make up a variable-length ladder line circuit to work with Cecil's 130 foot LL-fed multiband antenna (http://people.delphi.com/cecilmoore/mystery.htm) and would like to bunch up all the approx 32 feet of LL inside a plastic trash-can or yard building sort of "cabinet". With all that LL inside a small volume I need to worry about getting the coils too close together, and don't really have any idea how far apart to keep them. I am guessing 2-3 x the LL spacing, but I wonder if anyone has a better guess???

Anybody know how the field falls off with distance?

In that case, you may benefit from shielding inside your set (foil on the inside surface of the cabinet?).

You may also benefit from a 75-ohm resistance pad (or 300-ohm) in your antenna line to avoid set overload.

An external rabbit ear / loop combination may be more convenient than a loop mounted on the back of the set. You sure don`t need gain, and the resistance pad should take care of mismatching enough to minimize reflections (ghosts).

Spectrum analyzers can easily fool you when looking at pulse or wideband type spectra. One reason is the scanning nature of the spectrum analyzer. For example, suppose your analyzer scans at a 60 Hz rate, and that there's a narrow pulse type interference occurring once each cycle. The pulse will produce a very broadband spectrum, but what you'll see is a "carrier" or a group of lines whose distance from the beginning of the sweep will stay fixed, pretty much regardless of the frequency span or resolution you've chosen. I suspect you're seeing a similar phenomenon.

No signal that lasts for a finite time produces a single frequency. And a spectrum analyzer would have to observe each frequency for an infinite length of time to truly show the frequency domain content of a signal. So what you see is an approximation at best.

Anyone interested in learning more about this topic should read _Modern Spectrum Analyzer Theory and Applications_ and _Modern Spectrum Analyzer Measurements_, both by Morris Engelson. I think they're available from Artech House.

I use a rule of thumb of six inches. Keep all ladder-line at least four inches away from all metal and other ladder-line. Something that works well is to spirally loop the ladder-line around a non-conductor with six inches of spacing between adjacent loops.

I actually wound up not needing a 32 ft or a 16 ft loop on my setup. I needed to vary the length from zero to 23 ft so I have 5 loops of 1, 2, 4, 8, 8 ft. which are very easy to manage. Only the 8 ft loops require a support.

I'm on a city lot, in the big city of Houston no less. No problems here. Actually, that antenna took less room to put up than many of my other ones. The radials are only 32-33 ft long so at a 36 ft mount they are well off the ground at the ends and can slope quite a bit. Tne support was simple. A radio shack 36 ft pushup mast. The antenna itself I made from an old 5/8 cb antenna which was well made and had a good solid base section. I just extended to 32 ft with smaller tubing and a car whip on the top. Was very flexible and self supporting. No guys required. My 160.80,40 dipoles on a single coax takes much more room. 440 ft of wire in the air. It snakes all over the property though the trees. For this lot, a ground mount is harder to deal with as I don't have the proper yard room to lay out radials in all directions. No problem with the GP. I'm sure many don't want to deal with something like that, but I just feel it's my duty to tell them what they are missing. Trying a ground mount with only 8 radials is a sure way to build a dislike for verticals. I didn't like mine with 32 radials. It was mediocre at best. About equal to the dipole at a distance. If I was lucky, that is... MK

"Until the treaty is modified, however, it is not very responsible of
you to be advocating disregard for it."

Coders have perpetrated injustice for no-coders for most of the last 87 years! They`ve done it through tyrannical organization. No-coders had no organization.

It`s now obvious that the coders` position is indefensible. So, what is their reaction? Obstruct and delay.

No-coders want all mandatory code ended here and now. No more delays!

Best regards, Richard Harrison, KB5WZI

For all practical purposes, the code requirement has been ended. 5 wpm is being maintained in accordance with international treaty. Your continued press for an immediate end without consideration for the normal process accepted by society in general is unbelievable! You are advocating breaking the law! And all for a selfish reason!

Having a common entry point into any organized effort is not an indefensible position. It brings order and a sense of community to the effort. People who refuse to enter on a common basis with all others have only their selfish interests at heart; not the common good of the group.

Injustice is always the hue and cry of those who wish to change something for their own benefit without working to acquire it. When translated literally, it is a common plea for the welfare concept of society. I exist; therefore I deserve it!

Defensibility is not a factor in setting requirements for the hobby of amateur radio. It is a hobby. It is not a social experiment; nor is it a welfare program designed to accommodate those who refuse to earn their way.

The no-coders and freebanders have no concept of the hobby of amateur radio. All they have is the I want it attitude. It is unfortunate but they have gained sufficient numbers to prevail. That says little about the state of amateur radio but says magnitudes about the state of society in general. Sad.

So, when are you going for your Extra Richard?

Just thinking out loud. My roof is about 14 ft. off the ground. If I installed a 16ft bottom section guyed at the top by the four ground plane wires and ran 33ft of self supporting aluminum tubing up from there, would that be mechanically sound? I could mount an SGC-230 at the feedpoint just under the ground plane and work 40m-17m. Sorry for asking but I'm a EE. :-)

: license.

Amen!

Instead of a graduation exam, we should think of them as an entrance exam. If you can prove you have the necessary educational prerequisites, you can join a vast hands-on learning laboratory. Once upon a time, the written test for the general class license was identical to the written test for the technician license. Back then, the novice class was still popular. The intent was clear: We'll let you start playing (with severe restrictions) if you'll prove you've started learning. We'll give you full access (as in, a significant part of each band) once you can prove you've mastered the fundamentals. (Note: ...except for having to pass 13 wpm to get past Technician status.) The test includes knowledge of what's expected of you, and you're expected to understand that well enough that whatever you do on the air, you will take your mastery of the fundamentals and your demonstrated ability to learn this stuff, and you *will* learn whatever else is required to assure that you meet the standards you're expected to adhere to. As an incentive, we'll give you additional reserved privileges on each band if you can prove you've learned more. That was the status quo when I learned about amateur radio, lo this quarter of a century ago now, and by golly, that's about what makes sense to me. (Let's not miss an important point, here--many of us seem to believe that the way things were when *we* got *our* ticket is the way things make the most sense.)

But nothing's really that simple, is it?

People who got their license earlier than I did remember exams that pre-dated multiple choice. They were expected to do things like draw circuit diagrams. Now, *if* one has learned this stuff the right way, it doesn't make much difference. If you've learned what a particular type of circuit has, you can draw the diagram if you need to. Or, you can answer a multiple-choice question about it. Of course, if you've been advised that you'll have a certain type of multiple-choice question, you may elect to take a short cut, such as identifying one essential characteristic of each type of circuit you study, so that you can recognize it when you see it. *If* you prepare that way (and there's nothing that says you have to) then you may get by without learning as much as someone who chose to focus on the material itself. Similar dynamics surround the existence of published question/answer

pools. And so, we argue about the "dumbing down" of amateur radio. Perhaps we'd worry about this less if we look at amateur radio as a place where those who have begun to learn can continue on, and learn more.

Even though it was part of the picture when I got into ham radio, I have decided that I do not like incentive licensing. It divides us, which makes us more conquerable. It's contributed to all sorts of elitism and controversy. More to the point, it fails to address what I believe the central issue should be: Has Joe Wannabe learned enough that we can trust him to put a 1000-watt station (sigh...OK... I know..times have changed... a 1500-watt PEP station) on the air on HF? If he has, then he should be issued a full license. If not, then we probably should provide some limited-privilege license which allows him a chance to learn by doing. I *liked* the old power restrictions and xtal-only restrictions for novices. I liked the CW-only restriction, too, for novices. The novice license *should* be a license which, by virtue of its restrictions, makes it likely that someone who has only begun to learn won't mess things up too much. It also should be a license which encourages learning--you know, I almost think it should be a requirement that novices run *only* transmitters they built with their own hands.

Part of me does not want to see CW testing go. Why? Because CW is very, very cool (I was a teenager back when I got that first license, and not only were things as done by the FCC the right way to do things, back then, but also, that's a very good word: cool) and I believe that if people must pass a CW test to be a ham, many more will choose to use CW once they're licensed. Then CW will continue to be an important part of amateur radio, and... I am *convinced*... that would be very beneficial to amateur radio. I believe the popularity of CW helps promote building and designing by learners who otherwise wouldn't make the leap to more complicated modes. Learning the very basic stuff that allows one to participate in building CW equipment then empowers one to engage in very effective communications, even with modest antennas. What a wonderful incentive to learn how to build! There is no doubt in my mind: CW directly benefits much about what is so fabulous about amateur radio. I'm pretty sure CW testing promotes CW use. Therefore, CW testing should indirectly promote a lot of what's great about amateur radio. (Someone--I think it was Jim, N2EY--recently posted a very good explanation of why CW helps us achieve the official goals of the amateur service. I recommend reading it. Consider it included here, by reference.)

On the other hand, when I ask myself, "What should we require as the minimum qualifications for access to HF?" I find that I must honestly answer that I believe mastery of the fundamentals should suffice. (Note: That's mastery up to 70-whatever % correct, like it takes to pass the test--not necessarily mastery of 100% of all radio fundamentals.) If one can show that one has mastered the fundamentals, one should receive full access to HF ham bands. If one can demonstrate only having begun to learn, and yet wants to be on the air anyway, we should accommodate that admirable desire with a license which bears serious restrictions, designed to encourage learning while reducing the risk of improper operation due

to ignorance. The restrictions should, in that case, include restriction to the mode of CW, and therefore, testing of CW should be included.

In all cases, we should consider a ham license to be a certificate of qualification which entitles us to access to the hands-on lab we all enjoy. Admittance into that lab should be just the beginning of our learning experience.

OK... there's my proposal for how things ought to be done. You can all work on shooting it down now. It won't be difficult... one need only point out that the FCC isn't interested in putting out any effort to achieve any goals with licensing except reduce their own bookkeeping requirements. (It's hard to believe this is the same government agency that tried so hard in the past to design schemes which they hoped would encourage hams to learn more, even if it meant a lot more work for that government agency.) Nevertheless, I will hope that someone takes the ideas I've outlined here (a two-tiered scheme including a CW-tested learner's permit for beginners, and full ham band access for those who've learned enough to really get started) and find ways to adjust the basic idea so that it might appeal to the FCC as well.

Source record: 171122

OK, I almost made through the whole month without asking a dumb question...

Years ago, when I was a teen-novice, someone suggested that I add salt around my ground rod and radial system. Being a novice, I of course did. I would also water and really soak the ground system prior to a planned night of DX-ing. Anything to help my 5 watts!

Now, I'm wondering if there is any benefit from doing either of those things. Dry, parched, rocky ground like we have in Texas probably needs some help...especially in the summer. I used verticals, end-fed long wires, and inverted vees back then. I had a short run from my rig and antenna tuner to the ground. I had a good radial system below my ground-mounted vertical. But no matter what, I was convinced that watering my ground improved my signal and reduced static.

Thanks for any info.

Hi--

Trees are not bamboo. According to Alex Shigo, one of my neighbors and one of the world's leading authors and experts on trees and tree diseases, Roy and the boys are dead right. Trees grow by adding a layer which extend both upward and outward each year. If your antenna support was parked at the 60' level ten years ago, that's where it's gonna stay. And, eventually, if the support was an eyebolt, the tree's layers will surround and cover it.

Imagine a life where you can't move in order to protect yourself----all you can do is cover up the things that happen to you. Most trees are democrats, and that's why bark-huggers hug them!

Maybe it was a case of an inexperienced, tense, overstressed op where he made a couple nervous mistakes- S T are straightforward, the E D could have been meant to be A and R (with poor timing and the middle dah in R missed)

So he could have meant to send STARDEC which may have meant "Starting descent"

Last time I rode a commuter plane into Los Angeles we had to let down through 10,000 feet of solid grey blinding cloud cover. A few weeks earlier I had read in an article that airline pilots had voted LAX as the most dangerous US airport due to congestion and overcrowding. So I knew what a beehive of activity we were flying blind directly into, depending totally on technology and the training and experience of the pilots and the busy, overloaded air traffic control staff. In the little commuter plane we were like a small fish swimming among a school of sharks, the 747s and DC10s - in murky water, at that.
Flying doesn't bother me, but with that knowledge it was not a comfortable experience, even when I knew that it almost always works as planned.
The 1947 aircrew had to have been somewhat unnerved by it all and could easily have made CW mistakes, more so if the crewman sending the code happened to be fairly inexperienced. They almost certainly realized that such an outcome was a real possibility due to their lack of comprehensive information. With no more information, and no modern technology availailable they had to depend on only the elapsed time of their flight to determine that they had passed the mountains.

First I'd try just shortening the stinger rod, checking for resonance
to set it correctly. It should work out OK without removing a turn from
the coil.

Excellent! I was just about to pluck down the whole nine yards for
the MFJ. They look identical, with the exception of the power supply.
The Vectronics takes 8 AA batteries and can use their 240 VAC adapter,
while the MFJ takes 10 AA and uses a 120 VAC adapter. Not a problem!

Got one on order, now. Thanks Ken!

Preferred Customer wrote:
"One guy, in Charleston, West Virginia, pointed at a half-wave tower with 10 KW into it. The RF jumped at least a foot to his finger and came out his shin.---"

In 1949 I worked in a broadcast plant with two 5 KW transmitters sharing the same tower. One was on 950 KHz and the other was on 1320 KHz. Problem was the tower had been a 1/4-wave for a previous occupant around 700 KHz. It was almost a 1/2-wave for the 1320 KHz station.

We had to use a "hot stick" to open the shorting switches on the antenna ammeters for readings and to close them when we were through. The hot stick had a wooden handle. No fiberglass in 1949. RF had burned a carbon trench the length of the handle. No point to replace the handle. It would just be burnt again in a few days.

Every time we opened or closed a switch with the hot stick we were treated to a real fireworks display which nipped at our fingers. We were used to it and operated the switches very quickly to minimize the burn potential.

>
>Evan

Hi Evan,

The sharp bend in and of itself would not be lossy. However, it is a major discontinuity that will present SWR. SWR will bring its own problems and the measure of the loss you are interested is strictly implementation specific. The first consideration is the size of the bend in relation to wavelength. Standard rules for waveguides is that a bend sweeps with a radius of more than 0.1 wavelength. These rules are far more restrictive than would be encountered in typical Ham radio service. I doubt if this "rule" would be practiced for an 80M antenna (except by a purist who has the real estate to gently bend with a 24' radius). I would imagine that a radius of less than 0.01 wavelength would be problematic.

The best answer is try for yourself with a controlled bend in your own line.

Evan, K9SQG wrote:
"Today I read of large losses that result when you bend open wire line in a sharp bend."

Sounds mythical to me. Radio waves are guided by the transmission line and go where the line goes. If the impedance is upset by a bend, a reflection results and the line exhibits a standing wave ratio other than one. Only a slight increase in loss usually results because the impedance bump is usually small.

I worked for a number of years in a shortwave broadcast plant with many transmitters, miles of open wire lines, many of which had several right-angle bends, and many antenna switches and arrays, all of which had many right-angle bends. We had megawatts of power running through this mess and the losses were extremely low.

My question is:
What is proficient by international specification?
Is it one word per second or is it one word per hour? Maybe it is what any member country wants to make it be.

Best regards, Richard Harrison, KB5WZI

Don't play dumb Richard...it does not become you. You know exactly what it means. The US and several other countries have already set a level of proficiency that comes as close as possible to what the no-code group has advocated for quite some time. At the same time, they have stayed in compliance with international treaty obligations.

The US code speed has been reduced to 5 wpm. You also know full well that as soon as that next conference is held that a CW proficiency demonstration will in all probability be removed from the treaty. If elimination of CW is to occur, then it must be done according to the rules...not by advocating or even suggesting that we should just ignore the rules.

What helped greatly with my noise was to create a counterpoise under my car, by running several long pieces of tinned copper flat cable connecting everything I could springs muffler, frame etc. It reduced numerous types of noise AC, spark plug, and unknowns. I went from a S7-9+ nose level to a very comfortable S3, of course the antenna loves it.

"I am building a parabolic cylinder antenna. I want it to work around anything between 200 MHz and 800 MHz. It needs to be something relatively small (1m-1.5m x 0.4m-0.6m).

Dipoles with parabolic reflectors are not very broadband antennas. the reflector must also be rather large as compared with the dipole to get gain.

How about a helical if you want gain with bandwidth?

At 200 MHz, you can take a 1-inch diameter tube, 29.5 feet long and coil it to form 6 turns with an 18.5-inch diameter, 14.2 inches between turns (1/4-wave). This is backed with a 48-inch diameter reflector (screen?).

Polarization is circular.
Gain is 8 dbd at the center frequency.
Feedpoint resistance is 130 ohms.
Bandwidth is 200%.
At 600 MHz, scale down to 1/3 the size.

This information is from Arnold B. Bailey`s "TV and Other Receiving Antennas".

Best regards, Richard Harrison, KB5WZI

From: Richard Friedman <rchrd@rchrd.com>
Message-ID: <3A7912CC.EEC2AFE7@rchrd.com>
Source record: 171145

Wow. I seem to have sparked quite a discussion here. I really appreciate all
the input. The little reading I've done so far about Antennas (the late Bill Orr's
books, and the ARRL Antenna HB) have lots of really interesting info.
And it looks like there's lots of room for trial and error. There are
so many parameters involved, so there are no easy solution.

The problem is: I'm about to spend some $$ on my first station. (I'm a tech
but I should have the general ticket by Feb if I keep working on the code!)

What I really want to do is work dx on 20m-6m. And I have a new IC-706MKIIG.
I'm on the Pacific coast, so Asia seems a natural. But I'd like to work
Europe too.

The question is: what antenna do I buy? I'm starting out, so from what I've
heard from other hams, antennas are like golf clubs... you're never quite
satisfied so over the years you may accumulate quite a few.

My current thinking is to get an MFJ -1769 vertical to mount on the roof
of the house. It looks good so the neighbors shouldn't complain. I'll run
it up as high as I can get away with. The house is on a slight hillside, so from
the backyard the roof is pretty high up there. Pretty good line of sight
to the horizon for 180 deg west-north-east.

I'll may also get at 3-element M2 6m beam for mountain-topping.. I think I
can get it folded up and stowed in my camper van. Here a directional beam
seems to be the right choice for portable operations.

As I mentioned in the email that started all this, I get a lot of noise on
my temporary Diamond HV7A mobile antenna, and for SSB on 2m I have to
tilt it 90 deg to cancel out harmonics from TV sound.

What I don't have room for is a really big beam antenna, or a couple of
beams stacked. I was attracted to the MFJ verticals from good reports
on this newsgroup. But then began to wonder if I was going to be
disappointed.

So far the advice seems to be: there are too many parameters to predict
how its going to work. You have to try it. But answers to the original
questions seem to be going this way:

1. Verticals too noisy? Maybe. Depends. They see more sky, therefore
more noise. But maybe not. Depends.

2. Verticals prefer to talk to verticals? By the time the signal
gets to you its hard to tell what it looked like when it started
out. This may be more the case for local QSOs. But then again,
it depends. Its probably not worth worrying about.

Great discussion. I'm learning a lot! Thanks.

AFAIK,the open 1/4 wave cable is a short circuit for the concerning frequency.Though he should take the frequency of the tv-channel for the 1/4 wave calculation.

A normal dipole should be about 1/2 wave length. (a little shorter than that depending on the material that is used). If it's 1/2 a wave length the impedance is about 50 Ohms when fed in the center or the dipole.

If you use a different length dipole the impedance will be more or less than 50 Ohms. A Balun/transformer can change the impedance into 50 Ohms so your transceiver will not notice that the antenna is actually not exactly the right length, compared to the work frequency.

This is not the main reason for using a balun/transformer. The main reason is to feed the antenna which is designed for the right frequency into a point where the impedance is not 50 Ohms. For instance a half wave dipole that is 'end-fed' has an impedance of about 300 Ohms and can be fed with a balun/transformer 1:4.

A balun at the feedpoint does not affect the resonant length of a dipole.

What makes you think it does ? And why do you ask the question ?

It doesn't matter much anyway.

Regards, Reg, G4FGQ

It works, some call it a "ufer" or "Eufer" ground. Adding salt and
water in a small trench around the station ground improves the ground
conductivity.

Source record: 171151

Please notice that Andre said "parabolic cylinder", not "dish".

He may have mispoken and actually meant "dish", but I wonder if anyone in the amateur community has used an antenna with two (crossed) parabolic **cylinders** (i.e. without compound curves). I remember seeing such an antenna in some ancient IEEE journal or another, and I've alwasy wondered why it never saw widespread use -- it is much easier to fabricate than the conventional dish.

Foffe wrote:
"How come the commercial dipoles are shorter if they have a balun as opposed to when building a dipole with none, it`s longer?"

You normally make a dipole a resonant length, balun or no balun, for a specific frequency.

For free-space, the feed resistance of a 1/2-wave dipole is 75 ohms. At the low heights typical of amateur installations the feedpoint resistance is lower and a fair match can be made by directly connected 50-ohm cable.

Directly connected coax allows some of the antenna current carried by the shield to travel on the outside of the coax. A balun minimizes current on the outside of the shield.

Current on the outside of the shield causes radiation.

Shield radiation may make the dipole look like a fatter conductor on its shield-connected side. It would then have lower inductance than the dipole wire alone. Lower inductance would require a longer wire to reach resonance.

If the original proposition is true, that is antennas are shorter when baluns are used, it must be because radiation from the feedline makes the dipole wire look as if it is fatter and so must be longer to obtain resonance.

Best regards, Richard Harrison, KB5WZI

It does not affect the length of the antenna. Might I ask where you got that idea?

A balun simply does what it's name says, balanced to unbalanced. Baluns come in various transformation ratios, the most common 1:1.

H-P, now Agilent (I never will figure out how to pronounce this) had a
series of Spectrum Analyzer application notes. I have the complete
set around here someplace.

I did a quick look at their web site and found some of them,
unfortunately they didn't seem to have the one on pulse measurements
listed. :((

A lot can be inferred from the specturm if the analyzer is flexible
enough, which I doubt is true in this case.

Hard to say without knowing the weight and dia of the antenna. On mine, I had it attached to the house at about the top of the first section of mast. I had one set of "real" guys at about the middle, and the four radials at the 36 ft level, which also acted as extra guy wires. One thing you would need to consider is how you will attach the antenna to the mast. Thats why I like the pushup mast. I can lower it to roof level, and then stand on the roof to attach the antenna. Even using light tubing a 32 ft tall whip can be a bit hard to plant if you had to reach way up to lower it down onto the mast. Also if you attached the antenna to the mast and then tried to raise, it will likely be too tall with the mast included, and hard to raise. Mine used thinner and thinner tubing as it went up, and the top 4 ft of so was regular "car" whip with a little ball on top. Was a pretty light antenna for 32 ft tall. With strong 50 mph plus winds I never had any trouble. It would bend with the wind and not break or buckle. I've seen it almost sideways at times, but it always sprang back up straight when the winds were gone. I also reinforced the lower sections of tubing to make the bottom half stronger. I used mine on 17m as a 5/8 gp. Worked very well. Was my best 17m antenna by far compared to my wire antennas. I used a 24v relay to switch bands. A sgc tuner should work pretty well. If it could handle the high Z match on 20m, it might do well there also, as it would be a 1/2 vertical. I never got around to trying that band. MK

The old cushcraft R3 20-10 vertical would have been good for what you
want to do. But they don't make it anymore. For a "high" band 20-10m
vertical, I think the half wave designs are the way to go. That way you
don't require radials in general. The R7 is fairly decent for a 40-10
"1/2 wl" type of vertical. I'm not really familiar with the mfj version.
I think you have the right idea with the 3 el beam for 6m. MK

They don't /aren't. The only thing I can think of that would lead one to believe it does is that an undecoupled antenna uses the feedline as part of the antenna, and "could" look longer. But this is the feedline effects, not the antenna length doing this. If adding a balun makes an antenna "look" shorter, you can be assured the balun is doing it's intended job, and is "curing a common mode problem". If you had no problem before the balun, and saw no difference when adding it, you didn't have much of a common mode problem to start with. MK

Message-ID: <Nahe6.859$H51.10769@vixen.cso.uiuc.edu>
Source record: 171160

i am an apartment dweller, and i am taking my first stab at building an antenna out on my balcony. the antenna is for 2m, but it is not working correctly. when i key the transmitter (which is currently only a 5 watt ht), i get a very low swr of about 1.2:1, but i only see about 2.5 watts out. if i attach my rubber duck to the end of the feed line, i see about 1.5:1 and 5 watts coming out. also, if i disconnect the antenna and just transmit into the feed line, i get a full 5 watts with an swr of 2.5:1.

the construction is about 40 ft of coax running outside and connecting straight to the elements. i had a balun on there consisting of 10 turns of wire through a core, but took it off at the advice of a couple of other hams.

any ideas as to what could be wrong here?

2288. Followup on bad coax from Radio Works

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-01 17:47:15 UTC
From: Floyd Sense <sentek@sprintmail.com>
Message-ID: <Dihe6.2495$ln1.202794@newsread2.prod.itd.earthlink.net>
Source record: 171161
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment

A few days back, I posted an item about receiving some bad RG-213 coax from Radio Works. While they had UPS pick up the original cable, the replacement shipment was also defective.

When I called today about having them take back the replacement cable, they were just then inspecting the cable that had been returned. They told me they saw nothing wrong with the cable at all. I asked them if they'd looked under the several feet of black electrical tape I'd had to place over the damaged area so that it could be used for one rainy day (they hadn't noticed the tape - great inspection, eh?). They removed the tape and claimed they saw no holes and no defects. Admittedly, these were small holes, about what you'd make with the tip of a utility knife. However, one was large enough that when you flex the cable you could see the copper braid underneath. When I looked at that cable closely, I could clearly see that the jacket seam had not been completely sealed, resulting in the holes. They looked again and said they could see no damage. They ask me if I was talking about just something of "pin-hole" size (as if that somehow made it alright).

While they agreed to take the second cable shipment back, they refused to pay for the UPS charges as they had on the first, stating that it was their policy not to pay for returns a second time. The office manager then went on to explain that I was lying about the cable damage. I offered to put up $1,000 against her $1,000 to have a third party inspect the cable, but she explained how three people had already looked at it and saw no damage. Apparently, "third-party" has a different meaning in Portsmouth, VA?

I must say that I'm at a loss over this one. I've bought many, many hundreds of feet of coax over a 42 year period, and know a defective cable when I see it. It's bothersome to me that this outfit sees nothing wrong with the stuff they're shipping and would then accuse me of lying about it. What conceivable motive could there be for that?? If you do buy cable from these guys, for Pete's sake go over it very closely before installing it. If you don't know good coax from bad, here's some tips:

1. If the coax has lumps in it (like a snake that just ate), then it's BAD.

2. If the copper shield is badly oxidized (not shiny copper color) when you strip the jacket off to install the connectors, then it's BAD

3. If you run your hand down the cable and feel rough spots as if it had been drug along a concrete driveway, then it's BAD

4. If you can see the seam where the jacket was installed, look very closely and flex the cable to as to stretch this area of the cable. If you see pin holes in the jacket, then its BAD. If you can see the inner copper braid

through any of the holes, then it's REALLY BAD.

All of these conditions existed in the cable that Radio Works sent to me. They may also have all existed in the second shipment - I stopped looking after finding pin holes in the first 10 feet of the cable.

I've never heard anything negative about Radio Works before, and have no opinion on any of their many other products. However, I can assure you that at least one type of coax they're selling is just plain poor quality - make that defective. Furthermore, if you attempt to any such problems with them, you'll be subjected to the ignorance and wrath of their office manager (Judy?). I ordered replacement cable from The Wireman (no connection to them, but have received nothing but high quality cable from them over the years).

I agree with Richard. If you have common mode current on your feedline, the feedline becomes part of the antenna. When you use a balun, this extra part of your antenna is disconnected, making it effectively shorter. The resonant length with the balun in use should be close to the length predicted by formula or modeling program. Without the balun, you need less wire for the part you intend to be the antenna, because the feedline adds to the length actually making up the radiator.

Glenn Hansen has a long history of making trouble on the rec.radio.*
newsgroups.

In particular, he is well known for being the idiot on the newsgroups of
rec.radio.scanner & rec.radio.swap.

Thanks for taking him here to this NG & getting him off the scanning
NG, it's a welcome relief!

i recently received a 1000 foot roll of rg213 with the same defects that
you are describing (NOT FROM RADIO WORKS THOUGH) i returned the reel to
the sender and ordered a reel of belden cable although i paid a few more
bucks for the cable my headaches were gone

I'd use ferrite, preferably Fair-Rite type 43 (initial permeability 850) or equivalent. If the balun has enough impedance, no ferrite type will produce enough loss in a 1:1 current balun application to significantly affect your signal. However, 70 series ferrites (higher initial permeability) might get warm if 400 watts is applied continuously. 60 series ferrites (lower initial permeability) will work also but will give you less impedance per turn squared.

It's hard to get enough impedance with high frequency powdered iron cores like types 2 and 6. If you have the means to do the measurements, though, you might be able to make a self-resonant balun on a powdered iron core that would work very well on a single band.

2-1/2 inches is plenty large. I've run 300 watts CW through a balun made with a core slightly larger than one inch OD, wound with RG-174, with no problems.

Don't monkey around with the coil--just shorten the whip and measure with analyzer. Start with cutting about 5" off at first (you can't put it back on!) I forget what I had to cut off. I have a K-40 cut down for 10 meters and it works pretty good for what it is. I get wide band coverage 2.1 swr--so it is lossy. Hustler mast and coil works better, so does full size quarter wave whip.

Sidney, AB9BH wrote:
"---I get a very low swr of about 1.2:1 but I only see about 2.5 watts out."

Roy asked a cogent question. Are you sure the power and SWR readings aren`t switched?

If your sender were a low impedance source, its power out would depend on load conductance, if reactance is disregarded. So, low power output can indicate a high load impedance.

But, 5 watts into an open-circuit via the feedline with only 2.1:1 SWR is anomalous. The feedline and/or the measuring equipment are bad. An open circuit should show extreme SWR, and the net power to the feedline should be very small.

Best regards, Richard Harrison, KB5WZI

I need a parabolic cylinder antenna, it's a half of a cylinder used as the
reflector and a dipole located at the central axis of the cylinder, I know
this gain would be around 4-6(6-7dB), it's an experiment, it's not for
practical use

Andre escreveau na mensagem:
"I need a parabolic cylinder antenna."

My mental image is of a central slice of a parabolic reflector with a dipole and its reflector pointed at the parabolic strip.

What I posted regarding the full parabolic antenna also applies to the strip, sector, or truncaded parabolic antenna, only more so.

Cuprimentos, Richard Harrison, KB5WZI

A full-sized 1/4-wave mobile UKW antenna should not be too large.

The formula: Velocity equals frequency x lambda, where Velocity is 300,000 km per sec, and lambda is the wavelength in meters, gives a value of 2.05 meters for a frequency of 146 MHz.

So, 1/4-wave is 0.514m or 20.2in. Reduced for "end effect" the antenna length becomes: 48.8cm or 19.2in.

50-ohm coax will work well with this antenna, but the actual feedpoint impedance is somewhat lower.

Best regards, Richard Harrison, KB5WZI

2305. Re: What is a half wavelength vertical?

Thanks for the clarification. Yes, radials extending four wavelengths increase the ground conductivity in the region where ground reflection takes place. This would make the patterns of both the quarter and half wavelength verticals much more like the perfect-ground patterns. Both antennas would have much stronger low angle radiation if you can make a radial system like this.

Roy Lewallen, W7EL

Quite some time ago, I had a terrible problem with RF on the line on 10 meters, and nailed it by winding a few turns of coax with an air core (perhaps 4" diameter), and shunting it (braid on one side to braid on the other side of the coil) with a capacitance to resonate it on 10 meters. Use enough turns that it's almost self-resonant, or just make it self-resonant. It's at least an alternative to consider; certainly very inexpensive.

Cheers,
Tom

Source record: 171078
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment

Well, that is too bad.

It seems that the main issue with Radio Works is NOT that they have defective cable (since presumably they have nothing to do with the manufacture of the cable), but rather that they

1) did a poor job of inspecting it;

2) would not pay to return the 2nd bad cable (this REALLY shouldn't have happened because they REALLY should have looked at the 2nd cable more closely, based upon the experience with the first cable they sent you. You'd THINK that they'd want to be careful to ensure no future problems).

I think this kind of thing is important, and too bad for Radio Works because I've bought cable from them in the past and have been fortunate to not have problems. I was just looking to make another purchase in the coming weeks, but now due to your post I will look elsewhere, just to be safe.

This type of customer service is a huge pet peeve of mine.

I think that companies get away with poor service like this because people don't do anything about it. You have a bad experience with them, but then you and all your friends and aquaintences keep shopping there. Things will only change if people force them to realize they're not doing things right.

I was trying to buy a product from MFJ but had a question about it. I emailed them several times, and wrote them letters. They never did respond. Perhaps there is a secret to successful business that I don't know about, not being a businessman.

I've never owned one of the things, but have seen a few. One of our
Field Day denizens insists on having it set up in the CW tent. Doesn't
work worth a dang in real life.

One problem is that they interpret any noise burst or other signal as a
dit or dah. Stuff that a human would subconciously ignore drives them
batty.

> I suspect that most hams
> have much poorer fists than they'd like to admit;

Not in my experience. The thing worked perfectly as a monitor of what
was sent (it decoded the sidetone in the speaker) in our FD setups.
Most of the fists I hear are pretty good.

> that a good
> ear and skilled mind can gloss over their mistakes but older
> machines like mine cannot.

Don't know about new ones.

The only real use I can see for such things is to judge the quality of
somebody's sending in a test situation.

Later you mentioned a RAdio Shack meter and measuring the swr at the transmitter. Don't know much about the RS meter, but it may not be very accurate. Also on 2 meters you just about need to measuer the swr near the antenna. About 100 feet of good rg-8 cable or half that ammount of rg-58 will give a swr of around 2.5 or 3 to 1 with an open end. If you have about 400 or 500 feet of rg-58 the swr will be almost 1 to 1 with either a shorted or open transmillion line. This is due to the line loss in the cable. All the power is dissapated in the coax and by the time it gets to the end there is very little to be reflected and then the reflected power is lossed in the ruturn trip , so there is very little to measure.

A high swr will cause the meter to show more power output than there actually is. This may be why you are showing lots of power with a higher swr. You have to substract the reflected power from the forward power to get a goo indication of how much power you are actually putting out.

I am installing an Alpha Delta DX-EE in my attic tomorrow. I have about 30 feet of ridge line so I will have to run 5 feet on each end perpendicular to the rest of the antenna. At the corners where I bend the antenna at 90 degrees, what should I use to hold the wire? Can I just tie some nylon line onto the antenna wire? Or do I need some stand offs? Also, should I bend the 2 ends perpendicular in the same direction in an open box shape, or bend each one a different way like a zig zag? Thanks, Ken

> Commericial with BALUN = around 80 feet or so

The 80ft dipole is simply a shortened antenna and is a non-resonant length on 75m. It can be tuned to resonate by the feedline and a transformer. The balun is not appreciably shortening the antenna system - it is transforming the impedance, probably at a current maximum. For instance, the 27ft "matching section" on a 102ft G5RV transforms the impedance to about 12 ohms, resistive. If a 1:4 balun is installed at that point, a near-perfect match will be achieved for 50 ohm coax.

However, on 10m, 10-20 turns of coax on a 2L pop bottle is an appreciable percentage of a wavelength. If the SWR is not 1:1, it can certainly appear that the balun is "shortening" (or "lengthening") the antenna.

Evan

When I was doing a theory course for my ham radio ticket the tutor mentioned problems when using open wire feeders

Basically he said that it needs to be kept away from metal objects (but I guess you knew that one any way) and the other thing he mentioned was that any bends or changes in direction should be gradual... this was because if the bend is to sharp it will create an "impedance bump" (his words) in the area of the bend, which as Richard Clark, KB7QHC said will upset the standing waves.

Jens wrote:
"It is more important to get good results than to be small..."

A full-sized 1/4-wave mobile UKW antenna should not be too large.

The formula: Velocity equals frequency x lambda, where Velocity is
300,000 km per sec, and lambda is the wavelength in meters, gives a
value of 2.05 meters for a frequency of 146 MHz.

So, 1/4-wave is 0.514m or 20.2in. Reduced for "end effect" the antenna
length becomes: 48.8cm or 19.2in.

50-ohm coax will work well with this antenna, but the actual feedpoint
impedance is somewhat lower.

Best regards, Richard Harrison, KB5WZI

Is it possible to modify this antenna to get 75-ohm?
I need 75 ohm for my radio.
And is it possible to use isolated small wire?
and can i make a coil ?

This is not even close to real world. You must be referring to an antenna like the Alpha Delta 80-40. This uses a choke at 40M that looks inductive at 80M shortening the antenna to around 84' overall.

Your wattmeter most likely uses voltage sensing- the higher the Z of the load, the more power it will indicate. The only time it will read correctly is when the load is 50 Ohms resistive. Next, is your wattmeter good at VHF? When you terminate the wattmeter in 50 Ohms- what do you read? Where are you connecting the meter?

The swr seems to checkout. A dipole not close to the ground in terms of wavelenght is around 70 ohms. The swr meter is normally set for 50 ohms so the 1.5 to 1 is right. Guess that you are feeding the transmitter into the coax and then the meter and antenna is at the other end of the coax. If so, the 1.5 watts could be right if using rg-58 or maybe rg-8x cable.

> near the antenna i get swr of 1.5:1 and 1.5 watts power.

I bought some "RG-213" locally (Tucson) that was made by JSC. The stuff is total CRAP. I probably should have returned it but the seller is an acquaintence of mine and in a struggling business and it was the weekend when I was trying to install it.

There were bunched areas in the braid, what little of it there was, that could be seen through the jacket. I didn't see any pinholes but if I had, I certainly would not have used it. No way is this 'MIL-SPEC' but therein is the problem. The MIL specs aren't maintained anymore, so anybody can stamp RG-XXX on their product.

Fortunately this is only feeding an 80 meter dipole. For the beams I use Heliax and don't worry about it.

okay, that makes sense. but when i connect transmitter, swr meter,
rubber duck, i see 5 watts, and when i connect transmitter, swr meter,
feed line, dipole, i only see 2.7 watts. why is this? is the rubber
duck just reflecting a bunch of power?

From: Cortland Richmond <Cortland.Richmond@usa.alcatel.com>
Message-ID: <3A7A05C8.62AB3BB6@usa.alcatel.com>
Source record: 171102

A discontinuity on a transmission line has to be long enough on the line, and of sufficient difference in impedance from the rest of the line, to generate adverse reflections. This length will be measured in large fractions of wavelengths, not inches (cm) or feet (meters). One small discontinuity, except at VERY high frequencies, seems unlikely to be a problem at all. And if you are using any kind of matching or tuning device, including line sections, any effects will be swallowed up in the matching adjustments.

What's important with a balanced feeder is to keep it balanced with respect to objects along the way. IMO, this is MUCH more important than avoiding bends getting from here to there. However, if you bend copper wire sharply, it tends to break!

Cheers,

Cortland

With rare exceptions, if I get screwed I complain. I write letters, I make phone calls and I will complain in person.

Most businesses want to know about problems. Often I am doing them a favor by telling them about their deficiencies. I figure that when I voice my complaint, I'm probably speaking for dozens of other folks that have neither the time nor inclination to do it for themselves.

I often get refunds, free hotel rooms or meals, not so much as payoff for bitching, but as a thank you for pointing this out.

On the other hand, it is a two-way street. If I get exceptional service I say so and I'm a big tipper if the service is top notch.

I can tell you that this "e-commerce" thing is never going to fly (and apparently it isn't) until the sellers start taking email inquiries seriously.

There is a west coast seller of high-end seats for automobiles. I sent an email to them, as their web site encouraged, to get info on a pair of Recaro seats for my Camaro. These things sell for thousands of dollars and I gave them the color of my car's interior, the kind of driving I do, etc and asked for more info and recommendations. Never heard a peep. So I called them direct (no 800 no.) and got an answering machine. I got a promise that they would call be back. Never heard from them. Maybe they went out of business. I certainly hope so and I won't wonder why.

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3A7A09A7.68E606BF@eznec.com>
Source record: 171110

The comments about magnitizing and leakage inductance must be referring to an impedance transforming balun or a voltage balun. They're not a factor in 1:1 current baluns.

Leakage inductance is caused by the flux generated by the current in one winding which doesn't fully link the other. Measurements I've made on bifilar wound ferrite transformers shows extremely good coefficients of coupling -- very close to 1. This means that the leakage inductance is very small. (Actually, with many of the ferrites used for this purpose, the leakage impedance is more resistive than inductive.) If wound with coax (as I make mine), I would expect that even the very poorest coax you could get wouldn't have enough shield leakage to be measurable as a shunt impedance.

In a 1:1 current balun, magnetizing inductance doesn't appear in series or parallel with the circuit. Otherwise, a straight piece of cable with no core would be a worst case, having the lowest possible magnitizing inductance.

Impedance transforming baluns and voltage baluns are a different critter, though. These include a conventionally connected transformer (i.e., with one or more windings connected between the conductors) in one form or another. In that case, the magnetizing impedance does appear across the conductors and can cause a very noticeable change in impedance.

2333. Re: Why does a BALUN shorten antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-02 01:15:59 UTC
From: "Peter O. Brackett" <ab4bc@ix.netcom.com>
Message-ID: <95d1oaoki1@nntp9.atl.mindspring.net>
Source record: 171105

Foffe:

Assuming that the antenna system is "balanced" with and without the balun in place, so that feedline radiation is not involved, then the reason the resonant elements seem to be shorter with the balun in place is because of the finite non-zero [non-ideal] "leakage" inductance of the balun.

All magneticly coupled transformers [baluns or other types] have a finite non-zero leakage inductance [And, for that matter a non-infinite magnetizing inductance] which when combined with the distributed parameters of "resonant" antenna elements tend to result in shorter elements than for resonant antenna elements fed without a balun.

The "parasitic" non-ideal leakage inductance of the balun acts as a sort of inductive loading on the antenna elements.

Jens wrote:
"Is it possible to modify this antenna to get 75-ohms?

Yes, but the easy way keeps the same antenna and adds no coils and capacitors.

A match between two impedances can often be made with a 1/4-wave section of transmission line of the correct intermediate impedance. This is often called a "Q-section".

You are indeed in luck! The required intermediate impedance is the square root of the product of the in and out impedances. In this case they are 37 ohms and 75 ohms. The product is 2775 (ohms). The square root is 52.7 ohms, close enough to use 50-ohm coax.

We found the free-space 1/4-wavelength for 146 MHz to be 51.4cm or 20.2in. A wave travels more slowly in coax. In the common types such as RG8 the velocity factor is 0.66. So, 1/4-wave in coax of this type is 34cm or 13.38in. This length of coax between the antenna and the radio will make the antenna look like 75 ohms to the radio at 146 MHz. But the cable may not reach the required distance. To preserve the match, 3x this length, or 5x this length, or 7x this length will preserve the match. Even multiples of the calculated 1/4-wavelength line will repeat the 37-ohm antenna impedance and present this value to the radio as a load. this would not give the match you wanted.

Another way to get a match would be to use an auto-transformer (a tapped coil) to step up the impedance from 37 to 75 ohms, but the Q-section seems easier mechanically and electrically.

Best regards, Richard Harrison, KB5WZI

>"EN" and "R" are similiar so could simply be STaRdust DECending.

This is getting close to something that makes sense!

I examined the documentation available on the Web after watching the documentary about the Stardust on Nova. This problem is like some of the logic games I've done in magazines. Applying logic to the situation:

1) The flight crew believed they were close to the airport and were about to make a routine landing.

2) The message was entered in Morse code "quickly yet clearly". But in Morse code, _anything_ that's sent quickly can easily be misread. Yet on the other hand, the sender knows this, so STENDEC could not have been seen by the sender as a matter critical to flight safety or the like. More critical messages would be sent slowly, with as few ambiguities and non-standard acronyms as possible.

3) In every historical sense, later in-flight communication references to the flight itself and the speakers' names are generally abbreviated. For instance, a modern-day pilot may communicate at the start of the conversation with ATC: "This is Captain Robert Smith of Northwest Airlines Flight 345 from Tampa requesting permission to land." Later in the conversation: "Thanks, it's a great view of Manhattan circling around up here! NWA 3-4-5 Smith out."

My analysis -- "STENDEC" represents A QUICK REHASH OF THE INCOMING FLIGHT NAME AND THE WIRE OPERATOR'S HANDLE -- like in the example above.

STR would be a shortened form of Stardust casually reaffirming the flight name to the tower (like "NWA" above). And the name of the wire operator on the Stardust was none other than DENNis Harmer!

The dots and dashes of STEN DEC are literally the same as STR DENN.

[For debatability, it would be nice to know more about Morse procedures used in that era of aviation. For example, was it commonplace for a Morse operator to use a handle at the end of a wire? And what were some general protocol of communications between flight crew and ground when using the wire? If anyone knows something about these historical aspects I'd really be thankful!]

Our climate here in western Oregon isn't hospitable to wood being outdoors. But I've had an A-frame made from Douglas fir 2X4's up for somewhere around 20 years now, and it's still sound. I've painted it a couple of times with a couple of coats of stain, the kind used on siding and decks. It seems to do a good job of preserving the wood.

The vital thing, around here at least, is to keep wood from contacting the ground. Otherwise, termites and dry rot will make short work of it, painted or not. My A-frame sits on small concrete pyramids to keep it off the ground. I also keep an eye out for carpenter ants. They've used the guy ropes as a highway from the house to the yard, but so far haven't nested in the A-frame.

I just received my 100 ft roll of the same cable.
Upon close inspection, I see the seam where it was manufactured, I also see some very slight bumps in the cable, I don't think there is any "holes" I can see. But I will check some more.

Wes, N7WS wrote:
"So you`re telling me that if, for instance, I hang a small capacitor across a transmission line it won`t matter because it isn`t distributed down the length of the line?"

Ha, ha. Where was the smiley face?

We tried very hard to maintain line balance. We turned those right-angles without lateral tilt of the line in most cases. Physically we intersected the terminals of the lines at slightly different altitudes. Then, we connected them with vertical jumpers while carefully maintaining equal lengths in both sides of the line. We minimized capacitive stubs at the ends of the lines (and any other stubs not intended for tuning).

Best regards, Richard Harrison, KB5WZI

If it is given routine care and repainting, and is not in contact with the ground, it will last for many decades, just like wood on houses. Needs attention every four or five years, though. There are some wooden towers from before WW2 still in use in Singapore, and that is a much more aggressive climate.

hi,

I just finished building my first QRP rig; heck, my first transceiver of any kind. I am so excited that it works; I'm thinking of places I can take my radio now, where I couldn't before.

We always take our vacation on the beach each spring (Nag's Head, NC) and I wondered about operating from the beach. I fly there, so bringing supports such as a mast is not really an option. Bringing a roll of thin wire for a 40m dipole wouldn't be so bad, though. But then what would I do with it, just lay the dipole on the sand?

Anyone have any better QRP beach antenna suggestions?

tnx,

Go with a vertical. A vertical on the beach works great without
going nuts over radials.

I am not sure what commercial product you are referring to, however it is not the balun causing the shorter antenna. I would suspect some sort of loading is involved.

If you let me know which antenna product you are referring to we can start from a known point and go from there.

73 Fred W4JLE

And there used to be a nice kite shop in one of the beach-front malls in
Nags Head.
If you get one of their parafoil kites, be prepared for the need for strong
antenna wire.
Don't fly near any power lines.

Source record: 171030

oh man, of course; a kite! I should have thought of that.

Yes, the place we stay is near Kitty Hawk Kites, a very nice kite shop.
I even own a couple of their kites, including a parafoil. Probably best
not to use the stunt kite. ;)

To the folks that suggest a vertical, can you be more specific as to type,
since I assume you mean something commercially made. I'd like something I
can pack into a suitcase.

You know though, I'm already having second thoughts, picturing myself
sitting on the beach-- the ocean is pretty loud. I don't know if even
headphones would be enough. Well, worth a try and if not I could droop a
dipole on the balcony of the house.

tnx,

I may have found a good answer to my "which vertical" question...

The St. Louis Vertical.

Comments?

What would REALLY be cool is if I could actually use the pole for beach fishing, too! That would certainly convince my XYL to let me bring a pole with me. But a review I read of the SouthBend SD-20 (http://www.njqrp.org/mailarchives/mar2000/0008.html) said that it didn't have any fishing line ferrules on it.

>code/nocode is "moot".

Perhaps I used the wrong word there. What I'm trying to say is that the issue has been decided by the FCC. They no longer see any reason to keep code testing other than the treaty. This is clear from their actions and the wording of the R&O that caused the restructuring of 2000.

>
>Why do I think the treaty story is just another story to postpone the
>inevitable?

Because you are ignorant of the treaty and the history behind it.

> Because it fits so well with all the tooth and nail
>resistance to change the hardheads have demonstrated for half a century.

Resistance to change is not always a bad thing - all change is not progress. Why do you label those who don't share your opinions as "hardheads"? Don't they have a right to their views?
>
>I`m not familiar with the international agreement which is supposed to
>prevent further relaxation of Morse testing.

It's part S25.5 of the ITU treaty. It states that all persons wishing to have a license to operate an amateur radio station MUST demonstrate the ability to "send by hand and receive by ear, messages in Morse code". In other parts of the treaty, the terms "amateur radio station" and "Morse code" are carefully defined. There is also an amendment that says all signatory countries may waive the code requirement for amateur licenses which only allow operation above 30 MHz.

This part of the treaty has been in place since at least 1947. I think it may go back to 1936.

The treaty language requires some interpretation. "Send by hand and receive by ear" is interpreted to mean that the method used must require encoding/decoding skill by the operator, not a machine. "Messages in Morse code" means the test must be in International Morse (Continental) and must contain all of the

letters and numerals. "Any person wishing to have a license" means there must be a test or other objective measure of Morse skill BEFORE a license is issued.

> I expect it`s been grossly
>misrepresented to mislead the gullible.

Nope. The FCC makes the US rules, and the FCC has repeatedly stated that they cannot waive or eliminate the 5 wpm test because of the treaty. This was all explained more than ten years ago when the medical code waivers started.

> Many treaties direct conduct
>with no provisions of penalties for treaty violations. It must be that
>way when there is no mechanism for enforcement. It is that way for
>European poultry production and nuclear test bans. A lot of countries
>including the U.S.A. stick to a treaty as long as it seems to serve
>their interests and then freely deviate when the perceived interest is
>for violation.

Maybe so. The FCC and the State Dept. have repeatedly decided that violating the treaty is not in the best interest of the USA.
>
>I`d wager there is no need for the U.S.A. to require a 5 WPM code test
>by any international agreement.

You lose. Read and understand S25.5 - it's right there. And what matters is how FCC interprets it - they say 5 wpm is the bare minimum.

>There may be an agreement for some very
>unspecific testing for code operators on some parts of the radio
>spectrum. But, they are probably without meaning, penalty, or method of
>enforcement.

Nope. It's absolutely clear and unequivocal. That's why the next move is to change S25.5.
>
>The U.S. could today say no more code tests from this day on in this
>country and nothing could or would be done about it anywhere.
>
Maybe - but the govt. won't take that chance. The problem with such treaty violations is the precedent they set. If the US violates that part of the treaty, other countries may decide to violate other parts. Observance of the ITU treaty by signatory countries is actually very good, and the FCC doesn't want to mess with success.

I'm not saying I think any of this is "right" or "wrong" - just that it's the way things are.

"You get what you pay for" gets reinforcement.
While the seller and the consumers are feverishly defending
their stand, more off-shore crap has been successfully dumped
into our economy. As they point fingers at each other to place
blame, niether will admit they both got ripped off.
Unfortunately, the hard feelings will be around, long after the
bargain price has been forgotten.

2365. Re: Why does a BALUN shorten antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-02 12:51:18 UTC
From: "Peter O. Brackett" <ab4bc@ix.netcom.com>
Message-ID: <95eaesekt1@slb7.atl.mindspring.net>
Source record: 171038

Roy:

I stand corrected.

Thanks for that information, you are correct, distributed parameter "transmission line style" baluns, certainly have far less leakage inductance than lumped parameter, "transformer style" baluns. That was/is one of the reasons for the development of transmission-line style baluns, Ruthroff, etc...

I guess the question really is, what percentage is the balun's small leakage inductance of the antenna element's total distributed inductance?

If it is negligibly smaller than the antenna elements distributed inductance, then the effect of the balun's leakage inductance can be ignored in the length calculation for the element, if not, why then it will certainly result in a somewhat shorter element for "resonance".

Now my use of the term "negligible" is in the eye of the beholder so to speak, but generally the effect will be that, the higher in frequency one goes, the more the effect of balun leakage inductance on antenna length would become evident. i.e. the effect may not be noticeable on an 80 meter dipole but would be on a 70cm dipole, etc...

BTW... one measure of the ideality of conventional transformer's is the ratio of their leakage inductance to their magnetizing inductance, i.e. the higher this ratio is the better. For instance a ratio of more than 1000 is very desirable, and many transformer designs can achieve upward of 100,000 for that ratio.

I have often wondered?

Is there a similar measure of ideality for transmission line transformers? How does one characterize the non-ideality of transmission line or "current" baluns?

David,

Try a kite. Use thin wire supported from the kite line, not
the kite line itself. What kite to use? I have a 1/5 or so size
"French military box kite" that is difficult to bring down in a stiff
breeze, so it should be able to support a 1/4 wave vertical. The kite
is a triangular box kite with wings. A parafoil should be ok too. A
ground rod and a couple of radials for a counterpoise should set you
up fine. Watch out for lightning! Cut the string if you must, you
can always get a new kite and more wire.

David Snyder Hale wrote:
"We always take our vacation on the beach---."

A salient feature of the oceanside antenna is its location. A good ground connection and a good reflecting surface are near.

Any point in any direction has an r-f field strength which is the sum of a direct and surface reflected wave

The image antenna idea is especially applicable because good quality reflections are likely.

The image of the ground mounted vertical antenna makes the monopole appear as a dipole due to its image in the ground. As in a physical 1/2-wave dipole, a 1/4-wave ground mounted antenna will have both halves of the antenna in-phase. The result is energy concentration towards the horizon.

When a horizontal antenna is mounted above a good reflector, its reflected energy is of reversed polarity. This tends to cancel energy radiation at low angles and toward the horizon. How much so depends on height.

The ability of the vertical antenna to project and collect energy at low angles over the ocean, and the inability of a low horizontal antenna to do so, is a clear reason to prefer a vertical antenna on and over the ocean.

The War Department`s "Electrical Communication System Engineering" compares vertical and horizontal antennas. It lists virtues of vertical polarization as:
(1) A simple antenna is nondirectional in a horizontal plane.
(2) A short vertical whip may produce twice the signal of a horizontal antenna at the same height in the 20 to 40 MHz band.
(3) Over sea water, vertical polarization is much better than horizontal for low antennas.
(4) Vertical antennas are less disturbed at VHF from aircraft induced flutter.

Horizontal polarization benefis are:
(1) Some directivity can be obtained to reduce interference.
(2) Man-made interference is usually vertically polarized. Horizontal antennas are less likely to pick it up.
(3) In a not too dense forest, antennas and propagation are less affected by vegetation when horizontal polarization is used.

The respondents to David`s question of what antenna to use on the beach have said go vertical, and the above seems to confirm the advice so far.

Best regards, Richard Harrison, KB5WZI

You will problably have a litle of SWR because they ussualy are design to 60/70 MHZ so it's short, but there are some for 54 MHZ, so it depends on the model you are talking about.

Tom,

KMA makes a great little Log periodic just for 6m (KMA 5054). It looks a lot like a TV antenna in size and shape. The bandwidth allows for both SSB and FM use on the same antenna. I have used one for over a year and can highly recommend it for situations where Low Profile operating is needed. Or Just simplicity. There is No tuning with this antenna. assemble it, mount it, use it.

Find the specs for the coax to be used and cut to length.

> Will RG213 coax work and what power, voltage will it handle?

Sure. At appx 30-31 pf per foot you would need about 8-9 inches to make
a 22 pf cap. I'm sure you would need to tweak the length to acount for
coax differences. 4 inches ahould be close to 10 pf. Should handle legal
limit 1500w I would think. MK

IIRC early on in this thread it was stated that the cable was labelled "RG213 Type"

I have always considered "type" as in RGxxx Type or 2Nxxx Type to mean "It looks more or less something like the real thing" and treaded such products as highly suspect and most likely not meeting any sort of MIL or industry spec.

It's right up there with "tested", especially for semiconductors. Sure they were tested, that's how the manufacturer determined they were rejects.

> http://www.mindspring.com/~w6rca

Yes and no. I took mine down to use as a field antenna. Horizontal for SSB, a quick change to vertical and I'm good to go on FM. One antenna. No tuning. Many of the standard 6m designs that I have seen have too narrow a bandwidth to allow for this. I have heard of some users mounting it at a 45 degree angle for FM and SSB use. There would obviously be some loss for both polarizations, but it does allow for full 6m capability with a single beam antenna, and a single mounting configuration.

A single band LPA antenna like this is also nice for those with physical disabilities or no real enjoyment to climb high to keep fussing with antenna tuning. You can assemble this antenna on the ground, mount it and be done with it. That alone can be a huge bonus for some. I live in rain country and I have no worries about weather affecting my SWR. The real world forces compromises on many of us. This antenna design has some real advantages for some users.

As a comparison I now have a 3 ele M2 6m yagi installed. It is way too early to make any fair comparisons, but the KMA LPA seemed to have better RX. Maybe this is due to the higher FB. I do like KMA the antenna and would recommend to anyone that needs what it can offer.

Agreed! But one of the problems is that some folks want the entrance exams to be so easy and simple that they require no real learning or knowledge.

> Once upon a time,
> the written test for the general class license was identical to the
> written test for the technician license. Back then, the novice class
> was still popular.

The reason the Novice was popular was that there was a significant difference between the Novice requirements and those of the other license classes. When the General written was split into two elements (1987), the difference was reduced to the point that many newcomers went straight for the Technician. When the Tech lost its code test in 1991, it became easier to get than the Novice and became the "entry level" exam by default.

The current 35 question Tech exam is about as simple as the old 1970s Novice written exam. But the current Tech carries much more privileges and is renewable.

Exactly. Part of the process is imparting those values (personal responsibility and continued learning) on the newcomers.

> got *our* ticket is the way things make the most sense.)

My experience was slightly different. I was licensed in 1967, on the eve of the 1968 changes that came to be known as "incentive licensing".

Back then the structure you describe was just being put into place, amidst howls of protest by some hams. Under the system many of THEM had started out with, the Novice was for beginners, the Tech for VHF/UHF experimenter types and the General was for everybody else. A few pre-1953 OTs had Advanced, and the really knowledgeable hotshots had Extras. (There were only about 4000 Extras in 1967 - about 1.6% of the US ham population). The FCC changed the rules because they (the FCC, that is) perceived that the hams of 30-40 years ago were not technically knowledgeable enough. The FCC thought most hams of those days were learning oriented right up to the time the General arrived - then they tossed the Handbook to a beginner, bought a manufactured transceiver and stagnated. "Sputnik fever" probably had a lot to do with this.
>
> But nothing's really that simple, is it?

'Course not. There were lots of other dynamics going on - just like today. For example, many hams of the '50s and '60s bought rather than built because of the complexity of SSB and the rising tide of affluence back then.

> Similar dynamics surround the existence of published question/answer
> pools.

Exactly. The prewar exams involved blue-book essays.

> And so, we argue about the "dumbing down" of amateur radio.

Yup. Some deny it exists, despite all the evidence. Others say it doesn't matter. I say we can do something about it.

> Perhaps we'd worry about this less if we look at amateur radio as a
> place where those who have begun to learn can continue on, and learn more.

There has to be a reason to learn more. Some will do it because they are interested, of course, but others won't.
>
> Even though it was part of the picture when I got into ham radio,
> I have decided that I do not like incentive licensing.

I think the idea is a sound one. The implementation is poor, though, because the rewards for learning more do not correlate with the knowledge gained. A Tech can do all of the same on-air things as an Extra today - just not on all of the same frequencies.

> It divides
> us, which makes us more conquerable. It's contributed to all sorts
> of elitism and controversy.

There have always been divisions and levels of achievement in human activities. Ham radio is no different. One of the best things about ham radio is the wide variety of ways to become "accomplished" or "elite".

This is why awards, certificates, contests and other activities are so popular - they provide measurable proof of accomplishment. The license structure used to do that too. It still does, but in a much reduced fashion.

> More to the point, it fails to address

The FCC seems to agree. The main question then remains: What sort of testing is adequate evidence of Joe Wannabe being worthy of that trust?

> If not, then we
> probably should provide some limited-privilege license which allows him
> a chance to learn by doing.

And what you wind up with is very similar to incentive licensing! A graded series of tests, leading up to a full privilege license.

> I *liked* the old power restrictions and

> for novices. The novice license *should* be a license which, by

virtue
> of its restrictions, makes it likely that someone who has only begun
to
> learn won't mess things up too much.

Exactly. Those restrictions must be coupled with privileges that result
in reasonable rewards.

The restrictions had a beneficial side effect: A station that maxxed
out the old Novice privileges was within the building/buying ability of
many beginners. Not anymore.

> It also should be a license which
> encourages learning--you know, I almost think it should be a
requirement

And it does! But the FCC doesn't see it that way. So it is up to us who
know and use the mode to promote it, with or without testing.

>(Someone--

> encourage hams to learn more, even if it meant a lot more work for
that
> government agency.)

It's NOT the same government or the same agency. From about 1975-1980 onwards, the FCC has been slowly pushing for lowered qualifications and less admin work for themselves. One reason is less budgeting - another is being headed by career political types rather than career communications types.

> Nevertheless, I will hope that someone takes the
> ideas I've outlined here (a two-tiered scheme including a CW-tested
> learner's permit for beginners, and full ham band access for those
> who've learned enough to really get started) and find ways to adjust
> the basic idea so that it might appeal to the FCC as well.

The basic concept is right. The main thing is to rework it so it doesn't give the FCC headaches.

The biggest problem is that there hasn't been a major rethinking of the license concepts in decades. It's all been a slow patchwork job, fiddling with this, adjusting that, focusing on narrow issues instead of broad ones. The last real restructuring was 50 years ago.

How about this:

Divide each ham band into three subbands: Morse only, digital, analog phone/image. All licensees take a "Basic" test that insures they know things like safety and the regs. A Basic license gives you some low-power privileges but with restrictions like not being able to VE or control a repeater, and limited or no access to modes like SSTV. A Full license requires more written testing to address issues not tested in the Basic test, and you get more power and more modes. Access to the (very cool) Morse-only subbands requires a Morse test - sending and receiving, 5 or 10 wpm.

That way, the license privs match the test accomplishments. There could be more levels besides Basic and Full, too - say, Basic, Intermediate and Full.

Existing hams could get credit towards the new licenses based on their existing tickets. Or retest everybody over a 10 year period (you get one "free" renewal, then you have to retest before it expires or go off the air.)

The FCC isn't going to think of stuff like this. We have to do it.

How easy is the KMA LP antenna to use in a portable situation?
E.g. take it down, put in a camper van, put back together on a pole on top
of some mountain, cliff, beach, etc.
I see that KMA has both a 5 element 6m LP KMA5054, beam length 6',
and a 6 element 15' "Big-Six". I wonder how portable the bigger
one is.

Hmmm...I'll offer a guarded disagreement with Roy on this one: the inductance will be a bit lower because of the boom, but at least if it's an aluminum boom, I don't think the loss will be unreasonable. If you try it, try to keep it coaxial with the boom. Do you have any reasonably easy ways to characterize a coil like that which you can test with and without a pipe down the center? Maybe someone would like to make some actual measurements and post them. I would, but have too many other things going on right now.

Cheers,
Tom

Richard,

I have heard of some hams using the 5054 as a portable. The elements slide into the boom and are secured with a sheet metal type screw through the top of the booms. Taking the elements out is no big deal. I am more concerned the durability of the threads into the element from the sheet metal screws. One ham pulled these out and used a tap to put machine threads near the ends of the elements. He then used machine screws to assemble. Since the elements are aluminum, I think you would still have to be careful about stripping the threads after repeated assembly. I may look into swaging a threaded brass insert into the end of the elements for durability. I may even mount small sleeves on the side of the boom that the elements can be slipped into for quick and durable assembly. I think it is the basis for a great field antenna. It is such a simple rugged design, but for field use I'd like to come up with a different mounting arrangement for the elements.
Some folks use a bit of paint or tape to mark the elements and boom for re-assembly. It really isn't necessary though. The is no front or back till you get the elements mounted. There is enough stagger to the lengths, that I just stand them up next to each other. The two longest elements go on the back. The next two mount in front of that, and so on. The boom is really two booms close together. The elements are alternated on each boom. On element goes into the top boom, the other goes into the bottom boom. It is more complicated to describe than to just do.

When assembled, the feedline attaches to the front of the booms. One connector to each boom. Many just split the coax and attach the ends to the booms. I chose to mount a ferrite bead VHF choke balun at the front of the boom. I mounted the balun in a piece of gray schedule 40 PVC for waterproofing. I tie-wrapped this narrow little balun to the bottom boom. Barely noticeable from a distance. This makes for a more water proof connection for my needs, and reduces the chance of the coax shield coupling to the lower boom. The coax will have to be attached to the lower boom for a

foot or two to get back to the mast.

When I attached my elements to the boom I used Penetrox and stainless lock washers under the sheet metal screws. I also used several different colors of green paint to make it a bit more stealthy. The backdrop to this antenna is a couple of Douglas Firs. It mostly goes un-noticed by non-hamsters. After being up a year, I took it down and checked it out. Still snug and 100% functional. For home QTH I can recommend it without reservation. For field use, I have not tried it, but I think with a bit of thought it could be an ideal field antenna. For portable use, the existing boom is 6 feet long. That is going to be a personal call as to how portable that is. The elements themselves end at the boom so they are all 1/4 wave long. That makes them all less than the 6 ft long booms. The whole thing bundles up into a nice round package. No tuning/matching hardware to fuss with,get damaged, or lost.

I have no personal experience with the Big-Six. I would have reservations about using it in the field however. It is a much larger and heavier antenna, requiring much more extensive and heavier mounting hardware. Higher wind load too. More difficult to turn as well. This long beam would likely have a more difficult time working (or even hearing) off the sides or back. Making lots of spinning necessary. Really you would need a heavy duty mast and rotor to be practical here. IMHO it is probably too much of a good thing for simple, field use. The 5054 is a great all around compromise of gain, FB, weight and size. The armstrong rotor method would be no big deal here. I had considered using one of the Radio Shack, 3 ft fold over tripods mounted to a small sheet of marine plywood. I could park the front tire of my Land Cruiser on the plywood, put the mast and antenna in the tripod, then stand the whole thing upright. Sitting right outside the drivers door would make for easy turning. Another option is to put a mast mount on a fold down trailer hitch. Again the mast and antenna are put on in the horizontal position. Then stood upright at the rear of the vehicle. A brace from the luggage rack could take some of the lateral load off, and turning should not be too difficult.

I hope this was of some value to you and I wish you good luck.

Yes, but Ed in no way is short on inclusion of the theory. I`ll find my copy and look up the transmission line construction. There are many photos and drawings of the way things are done.

I was relating from my memory of the way we did transmission lines. It works. You can get imbalance if you let one of the wires run lower than the other. Unused connections on a line also cause upset.

I bought a Fritzel FD4 antenna about 4 years ago and it works great.
It's the 80 thru 10 meter ant.
Any of you who know alittle backgound about the maker of this type of antenna knows its no longer for sale. This antenna was also made in a 160 meter version. What I would like to do is make one for 160 and buy the Balun from Amidon, Inc. This is a off center coax fed antenna and I need to know the correct length for the 2 legs. Does anyone here know or have this type of antenna that could e-mail along the info to me.

Thanks,
Mike W4MJR

Well, they made no claim that the cable is Mil Spec. However, I think it's reasonable to assume that something sold as coaxial cable is at least capable of keeping water out of the inside, regardless of the manufacturer or price. Here's what Radio Works says about their RG-213 cable, followed by what they say about their RG-213 Plus, which is what I purchased.

"RG-213 is the standard 50 coax replacing RG-8 which was the popular choice for years. RG-213 is similar to RG-8 but is built to a much higher standard."

Now for the "plus": "There are always was (sic) to improve a product and that is what was done to RG-213 Plus. It features an improved braid and even better quality, non-contaminating jacket."

While the author may have been given to hyperbole, I think it was reasonable to assume that the stuff wasn't reject junk. If this stuff is their very best, I pity the guys who buy the cheaper stuff!

Yup. If ya ain't pushin' the envelope, yer not learnin' much. That's one mistake a lot of folksmake learning the code - they think they have to be perfect at, say, 15 wpm before they go near 20. The opposite is true - progress comes by trying speeds where you are missing a significant amount.

> I'd hoped the morse
> decoder would help in that speed band where I began missing
> things and thus loosing confidence.

The idea is good, but those things have not caught up with the wetware yet. (This is what drives some folks wacky - the idea that there are some things a human can do better).

> It didn't, but hope springs
> ...:o)

Worth a try, anyway. But to me it misses the whole point. It's essentially buying a machine to have your fun for you.

Hey! I plan to do some QRP from the beach this summer here on Cape Cod.
I'm going to try using kites and balloons to lift vertical wires over what
should be (near) perfect ground -- salt water! And, if the green police
don't catch me, I may try a home-made portable vertical over a local salt
marsh on 40 - 10 m.

Source record: 171066

The question is about sharp bends, not externally adding lumped circuit parts. Still, it's intersting to look at your scenario as ONE section of line with greater capacitance than the rest of the feeder. If we do _this_, adding a lower impedance (higher capacitance) section to a feedline won't bother things much until its length is some substantial fraction of a wavelength. And then it's a series matching section. (Or MIS-matching section -- grin!)

And of course a small enough capacitor isn't going to move things around much anyway. You'll get some capacitance each time you pass near a conductor. Unless you've arranged these so they are some substantial fractions of a wavelength apart, they won't really change the match (or lack of it).

Source record: 170969

I was wondering if anyone could give me a bit of advice. I work for a help desk that uses Vodafone's packet radio to send and receive credit card security numbers, I only recently became aware that the aerial for this is located in the same room where we work, no more than 6" from us.

I am not 100% sure but I think that this system operates on the same basis as a mobile phone, does anyone know of any regulations about safe distances etc. that this type of equipment should be kept from people, I find it very strange that it would be placed in a room full of people.

Sorry for posting here but I thought you would be the people to ask.

Thanks in advance

Dave : build and try the St. Louis Vertical. Search for it on the
web...I think there is a link from the NorCal QRP site. Good, easy
antenna to build and carry and folds down nicely.

Okay ... the original question was about sharp bends, but you changed
it to discontinuities in general and stated that they must be "long"
to have measureable effect I'm just pointing out that they don't
necessarily have to be long.

The dipole also has the advantage of not requiring radials to work properly. Verticals have lower angles of radiation and tend to work better for communications at a distance, like DX. Dipoles have a higher angle of radiation and tend to work better for communications relatively close by (up to several hundred miles). This may affect your decision. You might want to try the dipole and a home brew wire vertical for one band and compare them.

Wire antennas are fun to experiment with! Good luck and 73,

James,
As others have siad, try a simple dipole for one of the
bands your interested in, much cheaper than the 4-BTV, and
in general, will do a better job for you. Unless you put in
a good ground system for the vertical, you won't be happy
with it (no matter what 'they' say).
'Doc
PS - If you decide you want the vertical, take the dipoles
down and use them for radials.

Wes, N7WS wrote:
"I`m just pointing out that they don`t necessarily have to be that long." (runs of differing impedance as bump producers)

Exactly. It`s the abrupt impedance change which causes a reflection. Long abuses such as spacing transmission line wires in a vertical plane, too close to the ground, may cause a cumulative imbalance effect. That`s not good either. But, it`s the direct connection of a line or load of a different impedance from the transmission line of interest that produces a bump.

On the other hand, a tapered line section of more than 1/4-wavelength can smoothly create a transition from one impedance to another without much reflection at all. This is not popular I think because insulators of so many different lengths are needed to pull it off.

Best regards, Richard Harrison, KB5WZI

Which was stupid. Many people were unable to devote the time etc that it took to upgrade their code speed or knowledge of electronics enough to pass the higher level segments. Those Hams, after having their Novice license for a year or two, were unable to renew or get another license right away - so they dropped out of Amateur Radio. I can verify this, as I was one of those Novices (look up WB7AVH in a mid-70s call book). I never got back into the hobby.

Now, was THAT the intent of the non-renewable license? If so, it worked admirably - as I knew several other Novices at the time who also dropped out.

->Hey! I plan to do some QRP from the beach this summer here on Cape Cod.
->I'm going to try using kites and balloons to lift vertical wires over what
->should be (near) perfect ground -- salt water!

Use BARE copper wire and a fishing reel to adjust it to resonance. If the wire is BARE, then you won't get the bottom-loading inductive effect of the wire wound around the reel. To the transmitter, it is just a lump of solid copper at the base of the antenna.

Adam <digipoint@hotmail.com> wrote:
: A normal dipole should be about 1/2 wave length. (a little shorter than that
: depending on the material that is used). If it's 1/2 a wave length the
: impedance is about 50 Ohms when fed in the center or the dipole.

Actually, closer to 72 ohms in free space. If you move the dipole closer
or further away from ground, the feedpoint impedance can vary quite a bit.
The usual practice is to suspend the center about 1/2 wavelength above
ground and drop the end a bit - this gets the impedance close to 50 ohms.

: If you use a different length dipole the impedance will be more or less than
: 50 Ohms. A Balun/transformer can change the impedance into 50 Ohms so your
: transceiver will not notice that the antenna is actually not exactly the
: right length, compared to the work frequency.

That doesn't happen with a current balun.

: This is not the main reason for using a balun/transformer. The main reason
: is to feed the antenna which is designed for the right frequency into a
: point where the impedance is not 50 Ohms. For instance a half wave dipole
: that is 'end-fed' has an impedance of about 300 Ohms and can be fed with a
: balun/transformer 1:4.

End feed the antenna, and it is not a dipole. It is a half-wave, end-fed
antenna.

But, in your example, I would use 72 ohm coax with a 4:1 balun for matching.
My transmitter with the tube finals would handle 72 ohms quite well.

This is true for a current balun. A voltage balun is much less efficient. There was a study of this published in one of the ARRL antenna books, I forget which one.

: Current on the outside of the shield causes radiation.

Yep. If there are currents on the outside of the coax, at least for those due to leakage from the inside of the shield, then the coax is acting as part of the antenna system.

2417. How long can a ground strap be on a mobile screwdriver antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-03 05:42:57 UTC
From: Dick Grady <grady@wizard.com>
Message-ID: <es4n7t05tb641othet6f06ld0pkb85t9s5@4ax.com>
Source record: 170987

I am considering purchasing the High Sierra screwdriver antenna for my 1999 Chevy Tahoe. I want to mount it on the rear of the vehicle, because the Tahoe is wide and when I'm driving up dry washes here in the NV and CA deserts I don't want the antenna catching on bushes and rock out-croppings. High Sierra sells a mount which fits into a 2x2 receiver trailer hitch, which would place the antenna about a foot behind the back bumper. See the upper left photo on http://www.hsantennas.com/inpics2.htm . The mount hinges back to allow for opening the tailgate. So allowing for this lean-back, I estimate I'll need 2.5 to 3 feet of ground strap to reach the metal body of the vehicle. Is this length ground strap OK, or is it too long for good performance in the upper frequency HF bands?

>: AND we'll provide incentive in the form of a short license term and non-
>: renewable status.
>
>Which was stupid.

The FCC didn't think so for the first 25 years of the Novice.

The short term and nonrenewable status were done to emphasize that the Novice
was not meant to be a permanent license - that it did not represent a level of
achivement that one could stay at permanently or even for a long time. It was
meant as a learning tool.

> Many people were unable to devote the time etc that it
>took to upgrade their code speed or knowledge of electronics enough to
>pass the higher level segments.

True. In 1967 the term was extended to 2 years. In the '70s the license became
retakeable, and finally 5 year renewable.

>Those Hams, after having their Novice
>license for a year or two, were unable to renew or get another license
>right away - so they dropped out of Amateur Radio.

That was fixed by making the license retakeable.

>I can verify this,
>as I was one of those Novices (look up WB7AVH in a mid-70s call book).
>I never got back into the hobby.

There were hundreds of thousands of us who managed to upgrade, though.

Making the license retakeable but not renewable was the right move. Making it
full term and renewable removed any incentive to progress quickly, and the
Novice population of the bands began to drop because of it.

>
>Now, was THAT the intent of the non-renewable license?

As stated above - to serve as a learning tool - a step up, but not a permanent achivement.

Remember that before the Novice, ALL US hams had to do 13 wpm code and General - level written for their FIRST license.

>If so, it worked
>admirably - as I knew several other Novices at the time who also dropped
>out.
>
As noted above - that problem was fixed in the mid-70s If two years wasn't enough, take it again and get another two.

>: experimenter types and the General was for everybody else. A few pre-
>: 1953 OTs had Advanced, and the really knowledgeable hotshots had
>: Extras. (There were only about 4000 Extras in 1967 - about 1.6% of the
>: US ham population). The FCC changed the rules because they (the FCC,
>: that is) perceived that the hams of 30-40 years ago were not
>: technically knowledgeable enough. The FCC thought most hams of those
>
>Remember when you had to either have had a license before some given
>date, or have held a license for X years, before you could qualify to
>try for an Extra license?

Oh yes. Until the mid '70s it was two years. Then one year - then in the '80s it was dropped entirely. And the only experience that counted was as a General or Advanced.

I remember this very clearly because I was directly affected. I was a 13 year old Novice in 1967, then upgraded to Advanced in 1968. (I went for the General and the FCC examiner said "Try the Advanced" - and one did not say no to The Man in those days.) It was a piece of cake.

Then I went home and counted out exactly two years on the calendar, looking for the first test session when I could get the Extra. I was there in August 1970 and passed it on the first go.

Doesn't seem like 30 years.

--

Remember when you had to pass all the test elements for a given license in order at one session - no CSCEs?

Remember when any failure meant "go home and study for at least 30 days before retesting" ?

Remember when the exams were secret?

Remember the sending test?

Remember when the Technician and General used the same written test?

Sorry, Steve, that's not quit true- I have a large grove of large Bamboo, and two facts are clear; 1. it grows from the bottom, like grasses are supposed to, and, 2. the lower limbs are longer that the older, upper ones.

A peculiarity is that the "stalk" grows fast and tall, before the "limbs" start to come out at all. I have seen some over twenty feet tall, as bare as-- well, ---

Anyone within driving distance need some large (up to 3", it's a young grove) Bamboo for a Quad? I can spare a few.

Mike,

I've been using through-the-glass antennas for over 20 years now, and have been very satisfied with them. It is true that most mag mount antennas out perform the through-the-glass antennas, but there is a reason for it. The on-glass antennas are usually 1/2 wave antennas and the mag mounts are typically 5/8 wave antennas (remember the apple and oranges thing?).

Be aware that through-the-glass antenas do not work with many newer vehicles that have window tinting. Evidently there are some sort of metallic particles impregnated in the glass.

I have used the Larsen 2/70 for about 10 years now, and it has done very well. It's a little pricey, but worth the money.

I use the HS-1500 on my Chev Lumina Van (fiberglass body).
The trailer hitch its self is should be grounded to the chassis but install a short strap where it is bolted to the frame to make sure. Ground strapping the body parts to the frame under the vehicle will also help with noise. Mount it so the coil part of the screwdriver is above the roofline for best results. You could not have made a better choice. That HS-1500 is very high quality and has a superb finish.

What's wrong with using the hitch itself? Surely it is grounded to
the frame of the vehicle which should be grounded to the body. You
can always add additional ground straps from the frame to body. I had
a large nut welded to the top of the receiver (after drilling a hole
through the receiver) into which I have a bolt that I can tighten to
take out any slop in the receiver as well as provide a good connection
with the hitch stinger. This could also be done on the bottom (or
side) if you can't easily get to the top for drilling and welding.
Then you only have to be concerned about the connection at the hinge
which would be easy to strap across. If it's even necessary.

Source record: 171003

Cable "leakage" through the shield is not what causes a coax feedline to perturb a dipole's VSWR or resonant frequency. It's a lack of isolation between the half element connected to the shield and the outer surface of the shield itself.

When the impedance ratio between these two parallel-connected "wires" becomes small, they began to compete for dominance in detectable ways. In fact, with careful feeline trimming (or though random bad luck), it's relatively easy to create a condition where the feedline outer draws MORE current than the antenna half that's supposed to be doing the radiating--and the coax shield comes to dominate the performance of the antenna.

To prove this, a couple years back, I ran a test on a 15-meter dipole using a MFJ analyzer and some sensitive (amplified) common-mode current meters. Connecting a feedline roughly 1/4-wave in length with no balun to the dipole, I could force the outer shield to draw significantly more current than the half-element it was attached to. Moreover, by varying feedline length slightly, I could pull the antenna's "appearent" resonant frequency higher or lower by roughly 200 kHz or more.
Altering feedline length further, the current on the antenna's half-element element began to rise rapidly as the current on the feedline outer simultaneously dropped. As the current ratio changed to favor the dipole element once more, the antenna was no longer measurably perturbed by the feedline (the current ratio dropped to about -20dB with roughly 1/2-WL of feedline connected).

Installing a simple ferrite current choke at the feedpoint allowed any feedline length to be used without perturbing the antenna's measurable parameters. It made for a very dramatic demonstration for why installing a balun is a good thing!

Feedline "leakage" is usually only an issue in critical systems where several decades of port isolation is required. That's why we use double-shielded patch cables instead of cheap RG-58 used in labs and mini-hardline used in high-end equipment.

Hi Steve,

You have a point, but many horticulturists define a tree by its height - typically 12 feet. Bamboo can easily qualify in that regard in several weeks of vigorous growth. On the other hand, I've seen apple trees that are 80 years old that hardly meet that requirement (and not for pruning).

In many parts of the US, Holly is considered a bush, but here in the Pacific Northwest, I can guarantee you it is a tree (mine is going on 20 feet tall). Same goes for Lilac, I've seen Lilacs that have grown as tall as a small Maple (30 or 40 feet tall).

A high SWR can make the meter read high or low. In general if you are above the resonant freq a good bit, you will read lower than you are actually doing, if you are well below the tuned freq, usually you will read much higher than actual power. As far as the HT's power I wouldn't worry about the output if the SWR is ok. In general HT's are not very critical. They don't put out enough power to cause much damage if the mismatch is large. As long as below 2:1 SWR it should be fine in spite of the power readings. I don't think the readings are too accurate in his case for some reason. MK

> : balun/transformer 1:4.

Like Reg says the impedance will be much higher than 300 ohms. A 4:1
balun won't likely cut it. Also on a 1/2 wave endfed, you need to
consider the decoupling from the antenna to the feedline. This is one
reason why I tout the gamma loop for matching a base fed 1/2 wave. Of
all the different matching schemes for a 1/2 wl, I think the gamma loops
are one of the better designs as far as the decoupling from the coax as
is,without extra decoupling. Also the j pole design can do well if set
up properly. But the gamma is simpler to set up and doesn't require the
extra rods/stubs next to the radiator. Of course, even the gamma loop
can be improved as far as decoupling. A choke, or a decoupling radial
set 1/4 wl below the feed can further improve the decoupling from the
coax. But can be considered an option. I have a base fed 1/2 wave on 10m
that uses a gamma loop and no extra decoupling. Works fine. MK

Should it slope away from the sea, (i.e. high end furthest from the tide
mark), towards the sea, or parallel with the waterline, for best results?.

"The FCC didn`t think so for the first 25 years of the novice."

Then was then. Now is now. The FCC now has a no-code entrance to the ham bands. It doesn`t relax the obstacles to ham radio enough. There should be no code requirement for any ham band.

Morse code is more recent than the Latin language, but it is less alive and has less value. Latin is recorded in ancient writings worth interpretation and preservation. There isn`t much of that in Morse.

Why learn Morse? Only to fill some arbitrary regulatory requirement.

You can learn and practice Morse for fun. It hurts nobody. But require it? Morse is already phased out of every pursuit except amusement. Even last resort claims are more fancy than fact.

The idea that Morse enobles doesn`t prove that the same effort spent on something else wouldn`t be more enobling. It would very likely be more useful to spend your time on something else.

If you were to become accomplished in music you might entertain music lovers, but not on ham radio. You can talk on ham radio, but you would likely profit more from studying the art of conversation than learning how to say it in Morse.

The whole Morse argument is beyond odd.

The majority of the best conversationalists and scientifically astute have no interest in Morse code. If they liked Morse they might have become hams among whom Morse is still practiced. Why exclude them from any ham bands? They could improve the tone. They should be recruited.

Why exclude the inept in science and conversation who don`t do code? They might benefit from the amateur experience, and bring something to the hobby that is missing.

Numbers count!

With a large market for ham gear, you might benefit from lower unit pricing. With a lot more hams, congress would pay more attention to what hams wanted. Bigger is better. Minimum requirements is the way to grow.

Best regards, Richard Harrison, KB5WZI

I used a base-loaded CB whip for 10m FM (with a modified CB set plus
retuned CB 40W 'burner'). I didn't cut the whip or take turns off the
coil. As the CB antenna was inductive above its 'correct' frequency, I
simply inserted a compression trimmer capacitor in series with the feed
point (between the coax inner and the bottom of the coil), and adjusted
it for minimum SWR. I then measured the value of the cap (220p?). I then
replaced this with a fixed disc ceramic (500V) of the same value. OK on
40W (and I worked Jamaica and several US repeaters).

Ian.

From: Janice and Ed Senior <senior@best.com>
Message-ID: <95hv6p$2kf4$1@nntp1.ba.best.com>
Source record: 171015

Hi - I am looking for a suitable ground mount for a
light-weight vertical antenna.

The antenna is 25' tall, and weighs about 20 lb.
It will go on a base mast about 12' tall. Base mast
might be anything from TV mast to 1-1/2" galvanized.

Ideally, I'd like the whole thing to be strong enough
to be self-supporting. (The antenna section is.)

All I have come up with so far is the Gap "Quick Mount,"
which is a basic, light-duty tilt-over.

I know there are other items out there, such as tilt-overs
with cable winches (probably overkill for this). But I can't
locate any of them on the net; and HRO just gives me blank
stares.

Does anyone have any suggestions for suitable hardware,
and where to find it?

Thanks and 73, Ed W6LOL

I always hang my beach wire vertical from a very tall palm tree which are often found ringing those tropical beaches, and then I try to arrange the bottom end of the wire vertical to be in the shade of those same trees!

Then, all else being equal, after a couple of pina colada's, coupled with an exotic call sign, VPyxx, or whatever... the DX just comes rolling in!

Ahhh those tropical breezes... melodious CW floating across the tropical beach, "wall-to-wall" blue sky, fluffy white clouds...

What!

Where, am I... whose calling... wife!

Shovel the driveway! What....It's snowing again. Drat!

Sorry for stirring, and nothing to do with radio, but why do the
Americans invariably get the use of 'it's' and 'its' WRONG? Everybody
makes typos, but this is beginning to get to me!

FYI...
'It's' is 'it is'.
'Its' is 'belonging to it'.
It is (ie it's) an irregular use of the apostrophe. There are a few
others.

Ian.

Hello Richard.
Thanks for the support!
In the UK, we also have the 'Grocer's Apostrophe', as in 'APPLE'S
75p/kg' (BTW, we are no longer allowed to quote lbs and oz - BY European
Community LAW!!).

The 'Grocer's Apostrophe' is VERY common. It has not been outlawed.

Yet.

Unfortunately....

My other bitch is the use of 'You and I' in those situations where 'You
and me' is correct (sorry, Sir Cliff Richard, but you screwed up 'good'
in 'Summer Holiday'). Have you ever tried to explain the difference to

some computer whiz-kid (does that date me?)?

And there's 'less' and 'fewer'...

ENOUGH! This is hammerchewer radjio, and not a linguistic inquisition.
73 t'yall!
Ian.

You can only use bare wire on the nudist beach!
Best antennas for the beach are verticals (even shotened or loaded) planted on the beach, with elevated couple of radials. Kites and baloons are for those who have time to play with them rather than operate. For serious operation and contesting they suck, too much trouble, unless you have a crew to take care of them.

Yuri, K3BU
forget the alphabet soup, doesn't belong here

A natural for Nags Head would be a kite. You might need some help to fly the kite and operate at the same time, but.. Use some thin wire w/the string line. Best way is if you can find some WW2 surplus aircraft trailing ant wire. Fair Radio used to have it. Phosphor bronze if I recall, with a fiber core. Light, strong, flexible and already on a spool. Obviously, beware of power lines!!!!! Drive a ground rod into the wet sand near the water line, use an antenna tuner and have at it.

That is it Dick. Any slop could cause static and noise.
You can not depend on the hitch bolts to the frame to give a good path
either.
Metal parts that move and rub against one another is a possable source of
noise.
It made a noticable difference in noise when I straped everything to the
frame with wire.

Actually Dennis, I do believe that QSL's is the correct way to
pluralize QSL. 73's is the correct way to pluralize the number 73.
From Webster's: "apostrophe - a mark ' used to indicate ... the
plural of letters or figures" (figures meaning numbers)

There are two t's in the word "letter". That's an absolutely correct
English statement. QSL's, SASE's, and QSO's seem to me to be correct
for the same reason.

Just a heads up - information recently posted to the Towertalk reflector indicates that the Vectronics VEC-584B is probably NOT the same as the MFJ 259B. It appears to be equivalent to the older MFJ 259. Refer to the Towertalk Feb 2001 archive at www.contesting.com to read the postings.

Of course you realize that 73's is an absolutely incorrect term. 73 stands for, "best regards." 73's means best regards's. Don't know why 73's always grates on me like scratching your fingernails on a blackboard, but it does.

73's is the correct way to pluralize the number 73. Why can't it
mean "Lots of best regards"?

2465. Capacitance hats

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-04 05:33:01 UTC
From: jason_hsu@my-deja.com
Message-ID: <95ipieaak1@nnrp1.deja.com>
Source record: 170940
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.dx,rec.radio.amateur.misc,rec.radio.amateur.equipment

I understand that capacitance hats are a loading scheme used to work low frequencies with a shortened antenna. Capacitance hats are more efficient than inductive loading coils but aren't very practical for mobile use (due to the impact of the wind).

My questions:
1. How close to the top of an antenna must the capacitance hat be? Does it have to be at the very top, or can it be several inches below the top?
2. If I buy a Screwdriver antenna, can I use a shorter whip antenna combined with a capacitance hat if the longer whip makes the overall antenna height too great? (I live in an apartment, and I am interested in buying a Screwdriver antenna.)
3. Can I buy a capacitance hat from vendors?
4. Are there formulas that one can use to calculate various performance parameters of a capacitance hat?
5. What are the ramifications of different capacitance hat designs? Designs include a single wire, disk, circle with spokes, and spider webs.
6. How do you build a capacitance hat? I imagine that various mechanical issues (supporting all the conductors, keeping the capacitance hat from sliding down the whip, etc.) come into play.

2468. Ground plane for supplementing radials

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-04 05:55:42 UTC
From: jason_hsu@my-deja.com
Message-ID: <95iqsu$b44$1@nnrp1.deja.com>
Source record: 170943

QUESTION: Does supplementing radials with a metal surface connected to the antenna ground substantially reduce ground losses?

As I understand it, the ideal ground plane for a vertical antenna is an infinitely large conductive plane. RF emitted by the antenna strikes the ground plane, and the interaction results in RF currents in the ground plane. These RF currents need a conductive path to the antenna in order avoid producing electromagnetic waves that destructively interfere with the already existing waves. (How accurate is this depiction?)

Except when vertical antennas are used for mobile purposes or in environments with a highly conductive ground (like near saltwater), radials are used to approximate the ground plane by providing conductive paths to the antenna for the RF currents. The more radials and the longer they are, the better the ground plane and the lower the ground losses. The more closely packed the radials are, the less additional improvement there will be if an additional radial is added.

So let's return to my question: Does supplementing radials with a metal surface connected to the antenna substantially reduce ground losses?

It seems to me that adding even a small metal plane (provided by the vehicle's metal body in the case of mobile applications) to the radials would substantially improve things. In a network of radials, some of the RF currents will form between the radials and lack a conductive path to the antenna. Adding a small metal surface electrically attached to the antenna ground should be a substantial improvement. ALL RF currents that end up on the conductive surface have a conductive path to the antenna. This is like having an infinite number of radials with no gaps in between.

Assuming that you aren't operating mobile and CANNOT mount the antenna on your car and run coax to your shack, would you be able to substantially improve the ground plane by supplementing radials with the metal surface I described?

Has anyone done this? What do you think of these ideas for a metal ground plane?
1. Using a thin sheet of metal (perhaps a piece of aluminum siding)
2. Wrapping a sheet of linoleum flooring with aluminum duct tape
3. Aluminum foil (albeit reinforced with tape)

I mounted a Butternut HF6v (26') on a 8' section of 1" pipe driven about 6' into the ground...using 4 stainless steel hose clamps... the u-bolts were not nearly as secure. ..when the neighbor kids would leave it alone, it worked well.....and a WHOLE lot cheaper. Stood up to wind for 4 years... still would but I moved... and sold the antenna. Cut the end of the pipe you are going to drive in at a 45 degree angle with a hacksaw, it'll drive a WHOLE lot easier....

"Janice and Ed Senior" <senior@best.com> wrote in message news:95hv6p$2kf4$1@nntp1.ba.best.com...
Hi - I am looking for a suitable ground mount for a light-weight vertical antenna.

The antenna is 25' tall, and weighs about 20 lb.
It will go on a base mast about 12' tall. Base mast might be anything from TV mast to 1-1/2" galvanized.

Ideally, I'd like the whole thing to be strong enough to be self-supporting. (The antenna section is.)

All I have come up with so far is the Gap "Quick Mount," which is a basic, light-duty tilt-over.

I know there are other items out there, such as tilt-overs with cable winches (probably overkill for this). But I can't locate any of them on the net; and HRO just gives me blank stares.

Does anyone have any suggestions for suitable hardware, and where to find it?

Thanks and 73, Ed W6LOL

Hi Cecil,

For the general authority, consult :
"The Chicago Manual of Style," 6.10

Abbreviations with periods, lowercase letters used as nouns,
and Capitol letters that would be confusing if 's' alone were added:
Ph.D.'s x's and y's SOB's

There is something poetic about the cosmic conjuction of interest and
examples.

73's (so as to not confuse - 88's for the others)

Richard Harrison wrote:
>
> Why learn Morse? Only to fill some arbitrary regulatory requirement.

No,Rich, only to 1.) Learn to use a basic communications mode, and
2.) To qualify for an HF amateur radio license so long as that
qualification is on the books as an international requirement.

> You can learn and practice Morse for fun. It hurts nobody. But require
> it? Morse is already phased out of every pursuit except amusement.

Not so, there are still a number or ham radio CW traffic nets that meet
almost daily to pass traffic, mostly for training and practice purposes.
And it is still used on occasion to actually handle traffic.
During the last hurricane season where there were serious effects from
storms experienced in coastal Georgia and Texas, in both those
situations emergency nets handled traffic using Morse code when
conditions deteriorated to the point that SSB was no longer usable. Of
course other modes could have been used had they been in place and at
the ready, but they were not, and CW handled the traffic with no
difficulty, since there were hams present who were proficient in its
use.
Comes the day than no hams are proficient in its use, that won't be
possible. That is one reason some advocates of retaining a CW
qualification continue to promote it.

> Even last resort claims are more fancy than fact.

In your experience, I'm sure that is correct. All others don't share
your view, however, and I have personally experienced circumstances
where I would have indeed been pleased to have had radiotelegraphy to
fill in for commercial communications failures. But no CW gear was
available since it had been replaced and phased out years earlier. I
don't advocate that it not have been phased out, that was the only
logical action. But in ham radio it is different. Our mission, at least
those of us who consider ham radio as anything more than "Just a hobby"
----those of us who believe it to actually be a viable backup
communications service to serve on those rare occasions when failure
call it into play---- know without doubt that Morse on radio is a
viable and potentially valuable resource, still. Even in the face of all
that has come in the recent past. Why? The answer is simple-
Radiotelegraphy remains as the most simple, basic, and most easily
implemented means of radio communication yet devised. *IF* there are
operators available who can use it.

> The idea that Morse enobles doesn`t prove that the same effort spent on
> something else wouldn`t be more enobling.

Not much in life "Enobles". Morse code does not, except in the minds of
some of its opponents. But nothing else is the equivalent of knowing and
being able to use Morse.

> It would very likely be more
> useful to spend your time on something else.

Many people feel that way, and that is certainly their right. And it's
nothing new.

> If you were to become accomplished in music you might entertain music
> lovers, but not on ham radio. You can talk on ham radio, but you would
> likely profit more from studying the art of conversation than learning
> how to say it in Morse.

Until you developed a bad case of laryngitis. Or were too far from your
intended recipient to shout and had no other means to contact him except
Morse. Unlikely, of course.

> The whole Morse argument is beyond odd.

Yes it is. The most odd part of it is that so many who should, and
probably do, know better claim that Morse no longer has potential
communications value.
Just because it has been around a long time and there are many other
more modern modes and methods.

> The majority of the best conversationalists and scientifically astute
> have no interest in Morse code. If they liked Morse they might have
> become hams among whom Morse is still practiced. Why exclude them from
> any ham bands? They could improve the tone. They should be recruited.

It has always mystified me that so many individuals who can learn so
much are put off by so little learning as Morse code represents. When I
decided as a kid to become a ham, I don't think it would have stymied me
if they had required me to learn Greek. For darn sure Morse code didn't.

> Why exclude the inept in science and conversation who don`t do code?
> They might benefit from the amateur experience, and bring something to
> the hobby that is missing.

Who excludes one who decides he doesn't want to learn something that is
really simple but takes a modest amount of time and effort? The person
himself! Why exclude him, indeed!

>
> Numbers count!

Any mathematician will confirm that statement.

> With a large market for ham gear, you might benefit from lower unit
> pricing. With a lot more hams, congress would pay more attention to what
> hams wanted. Bigger is better. Minimum requirements is the way to grow.

I've always been one who felt that it should be only as difficult as necessary to obtain a ham radio license, and never more difficult than necessary. As a practicing Volunteer Examiner for the first eight years of the new VE system I always put that exact philosophy into practice, and there are many licensed hams who were tested by my team who will confirm that. I am not a "big" CW man, by any stretch of the imagination. I do believe firmly, however, that all ham radio operators should feel the responsibility to take it onto themselves to learn to use the most basic and most simple mode of radio communication.
Any ham who cannot operate effective CW is not an accomplished ham, whatever his other accomplishments. CW is BASIC radio communication.

Hello,

I wish to realise a discone antenna, but i don't know how to calculate the dimensions.

Thank you to help me.

Sorry for my English.

Francis

True, Dick, true.
I must confess that even I occasionally fail to use 'perfect' English.
Sometimes this is in keeping with common useage, and occasionally
because of sheer ignorance. However, there is no need to invoke
'exceptions' in the case of 'its' and 'it's'. 'It is' is 'it's', and
'its' ain't. Anything otherwise is simply wrong, even in 'American'
English.

Regarding the 'you and I' syndrome, I have occasionally had arguments
with otherwise intelligent people who insist that you ALWAYS say 'you
and I', even when it is the object or indirect object in the sentence.

Cheers,
Ian..

The acid test is to drop the "You and" part of the sentence; If what is left
is not grammatical then you need to use the alternative personal pronoun.
Add back the "You and" to the sentence, it's now correct.

Perhaps you would refresh my memory on the "Summer Holiday" reported error.

"to go boldly" OR "to boldly go"

The rules were changed recently, by whoever it is that sets himself up as
the arbiter of the living English Language

>for the same reason.

Sorry, but I can't agree with Webster on this point. I cannot see the
need to use an apostrophe when adding an 's' to indicate a plural. I
suspect that Webster is simply following increasingly common usage in
the USA rather than correctness. (Yes, I know that 'common usage'
eventually leads to 'correctness').

The RSGB have an approved style of 'grammar' to be used when writing for
their numerous publications. For example, you should always use lower
case where possible, and no 'points' except where the abbreviation could
be mistaken for a word, ie (not i.e.) tv (not TV), i.f. (not if or IF).
It seems to work well, and I use this style for all sorts of things.

The use of the ''s' to indicate plurals is OK in Dutch (on the rare
occasions where this is used instead of 'en'). Surprisingly, they DON'T
use the 's on the rare occasions where they use the 's' to indicate the
posessive. In Britain, we have what is known as the 'Grocer's
Apostrophe' (because of its frequent use on boards outside grocers'
shops when the plural is indicated). Then there's the question of the
'Grocer's Tomatoe/Tomato's and Potatoe/Potatoe's'. (I believe that a
notable American once got THAT wrong!).

While (Napoleon?) said "The English are just a nation of shopkeepers", I
must conclude that the Americans are a nation of Dutch grocers.

73 (not 73's or 73'S),
Ian.

> baluns?

Transmission line transformers can be evaluated like any other kind. When conventionally connected (that is, with the input and output taken across windings), their nonidealities have the same effects as in any other transformer. The main advantage to a transmission line transformer in these applications is that you do get an extraordinarily high coefficient of coupling and consequently small leakage impedance. And in cases where the winding length is a significant fraction of a wavelength, there are advantages to maintaining a constant impedance between windings.

The 1:1 current balun is connected differently, however. It can be accurately described as a common mode choke, with each winding in series with one conductor. The lack of concern about magnitizing inductance affecting the differential impedance isn't because it's a transmission line transformer but because of the way it's connected. You basically want two things from one of these. One is a high common mode impedance. This is of course accomplished by maximizing the winding impedance, which is one of the things you want to do with a conventionally connected transformer -- but for a different reason. In the balun, the balun's very ability to balance currents depends on its common mode impedance relative to the impedance of the external circuit. Leakage inductance or impedance is similarly undesirable as in a conventional transformer. Here, it manifests itself as a series impedance to differential currents. But as I mentioned, it's seldom a concern, since it's generally very small because of the transmission line windings.

The way I like to evaluate a 1:1 current balun is to connect an unbalanced signal source to the input. To the output terminals I connect equal value resistors to ground, at the same physical point as the ground side of the balun input. I judge the balun by its ability to

produce equal voltages or currents across the two resistors. A good voltage balun will also show up good in this test. The second test is to connect the output side of the "hot" winding (the winding whose input end is connected to the hot side of the input) to ground, and the output side of the "cold" winding through a 51 ohm resistor to ground. A perfect current balun would deliver the full input signal across the resistor. (A voltage balun would not.) An inspection will reveal this to be a simple polarity reversing transformer. It represents the worst possible case of a current balun attempting to deliver equal currents into the worst possible imbalanced load condition. In this test, conventional transformer analysis can be applied, and leakage and magnitizing impedances will have the effects you'd expect on input impedance. A current balun won't usually be subjected to this severe of a load imbalance, but it's a good worst case test to use in comparing baluns.

Kevin, W9CF, has written an excellent treatise on baluns, and particularly their connection at the input or output of a tuner. You can find it at http://fermi.la.asu.edu/w9cf/articles/balun/index.html. I highly recommend it.

They're context-sensitive. :-)

My favorite is the continual mix-up of 'principal' and 'principle'.

"James' principal reference for antenna design principles is still
John Kraus' book on the subject".

Very simple explanation: Our ancestors had to choose between creating a new word spelling or deriving meaning from context. With some words they chose one way, with other words, the other. Personally, I think they achieved a reasonable balance. There are something like 50 usages of the word "run". I prefer that to having to learn 50 different spellings of new words. Likewise, in the example above you have three different spellings of the same pronunciation. English already has enough words and/or pronunciations. It's more efficient to derive meaning from context than to try to increase the number of words and/or pronunciations.

If the coax feeder is 1/4-wavelength long and the braid is properly grounded
at the bottom end there will be a very high impedance at the top and very
little current will flow into the braid.

Will this prevent radiation from the feeder just as the choke balun is
intended to do?

With "two t's", Cecil quoted the exception and made that the rule.

Really there are no rules, only customs - but if we want to communicate with readers, we do well to follow the customs that they expect. Unfortunately there are several different customs, and lots of would-be rule-makers.

Also the rules, such as they are, were made for "art" writing. Modern commercial and technical writing is full of things the old rule-makers never had to handle.

A consistent and workable policy is to use capital letters for abbreviations and acronyms, with no abbreviation marks unless they are needed for clarity. If you don't need an apostrophe in the plural of he fully expanded form, you don't need one in the plural of the abbreviation either.

You don't *need* an apostrophe in "QSLs", "SASEs" or "QSOs" because there is no doubt about the meaning. "Two t's" is one of the exceptions where you do need one - and anyway, it isn't an abbreviation.

>The RSGB have an approved style of 'grammar' to be used when writing for

>It seems to work well, and I use this style for all sorts of things.
>
RSGB's rules changed, several Editors ago. The lower-case abbreviations

rule never made complete sense, because it regularly had to be broken for "if" in a radio magazine. RSGB now follow the modern convention of using capitals for abbreviations, with no points, so it's now "TV", "IF" and so on.

All kinds of other unnecessary punctuation marks are disappearing too. Points are disappearing after a person's initials - we don't *need* dots to tell us they are abbreviations. In mailing addresses, commas are disappearing after street numbers and from the ends of individual lines. Nobody misses them unless they are needed for clarity (as in 42, 42nd Street).

Now look what you've all gone and done - it's Sunday afternoon and you've pitched me into work mode!

Ah! only Fowler (1926)*, with his relaxed attitude,
no fool to be chained by dogma, got it right,

see POSSESSIVE PUZZLES and PLURAL ANOMALIES

The English Language is a living language,
like it or not others will change it to suite themselves,
and whilst they remain in the majority you can like it or lump it,
but change or freeze it you won't (will not).

> There are two t's in the word "letter".
>That's an absolutely correct English statement.

In a Living Language there are no ABSOLUTES.
Absolutes only occur in dead langauges;
languages that can no longer be changed to fit their purpose in daily use.

>QSL's, SASE's, and QSO's seem to me to be correct
> for the same reason.

Try 40s and 50s to indicate the decade of years, no apostrophe required.

Didn't mean to add to the confusion, but let me try to clarify.

I believe the vectronics link k5qwg mentions is in error. That does not resemble the unit being sold by Radio Shack. See the picture of what's being sold by Radio Shack at

http://www.radioshack.com/product.asp?catalog%5Fname=CTLG&category%5Fname=CTLG%5F001%5F002%5F001%5F000&product%5Fid=940%2D0683

I've taken the liberty to quote below what was said in two postings to the Towertalk reflector.

"I got mine yesterday. Comparing it to the MFJ catalog description, it looks like the Vectronics model is an older and less sophisticated version of the MFJ 259B. When you turn it on the Version is 1.1 and copyright 1998. It might be comparable to the original MFJ 259. It will measure SWR and the Magnitude of the impedance. I understand the MFJ 259B will tell you the reactance (X) and the Phase (+j or -j). Conclusion: The $149 Vectronics model is not an MFJ 259B."

"I notice two specific external differences -- the right-hand front panel meter is labeled "Impedance" on the 259B and "Resistance" on the Vectronics, and the 259B appears to have a separate ground terminal on the top of the case (for open wire line?) that is missing from the Vectronics."

2517. Simple VHF/UHF Dual Band Antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-04 15:13:47 UTC
From: Robert Shepard <rshprd@home.com>
Message-ID: <Lkef6.79740$P5.2207759@news1.rdc1.il.home.com>
Source record: 170891

About the time VHF/UHF dual band radios hit the market back in late 70s/early 80s, there was an article either in one of the ham magazines describing how to make a simple dual band antenna from a 21" Motorola NMO mount whip.

The process involved heating the lower part of the whip about 1/2" from the base, and adding (bending in) a couple of turns. It is the diameter and number of turns I cannot recall. I'm not even 100% sure about the 1/2" from the bottom, but it is the general appearance of the antenna.

The result was a 1/4 wave on 2M (slightly shortened) and I think a 5/8 or 3/4 wave on UHF.

Does anybody remember this antenna, and/or the exact way to calculate it's dimensions?

Please email response if possible.

Thanks,
Bob-KA9FLX

Hi Reg--

>If the coax feeder is 1/4-wavelength long and the braid is properly grounded at the bottom end there will be a very high impedance at the top and very little current will flow into the braid.<

True enough--assuming a clean cable run and an exceptionally good RF ground at the transceiver (which it seldom available). Then, the transformation you describe could occur, changing the critical line length from 1/4 to 1/2 wave!

Of course, there are many other factors, in addition to length, that may lower the driving impedance of the coax outer. These include mutual coupling to parallel lines, masts, towers, metal building components, etc.

Rather than "fiddling and diddling", it makes more sense to me to install a choke, break the common-mode current path, and have done with it. How difficult can it be to coil up a few feet of feedline?

The experience requirement was two years from the beginning of the Extra
license (1951) It was reduced to one year in the late 1970s, then eliminated a
few years later. It was never more than two years.

The old Amateur Extra First Class license of the early 1920s required one year
experience.

What you may be recalling is that, for a long time, anyone who could show that
they had held a US amateur license before WW1 would get an Extra.

The MFJ-259 (or its Vectronics equivalent) is an analog meter without the PIC-driven add-on features provided by the MFJ-259B. However, before ruling out the "plain vanillia" MFJ-259 as a good choice, here are a couple important things to think about.

First, keep in mind that SWR is about the ONLY antenna measurement any of these low-cost analyzers can perform (including Autek and AEA) that is not impacted by timing or impedance transformations in the antenna's feedline. Second, the MFJ-259 employs simpler circuitry and is less prone to calibration error.

I have both meters and grab the first one my hand lands on for most jobs. If you want advanced functions, break out the HP-8753 and do it right!.

No, actually it was a formal choice by FCC who reasoned that ability
consists of more than the first-time use of a lookup table.

I used a 2 feet diameter hat some years back. It was constructed from
#6 solid copper wire. A 2' diameter circle of #6 with 6 #6 spokes in
a hexagon configuration. It retained its shape very well up to... uhhhh...
whatever the freeway speed limit was ;-) It did deform a little when it
encountered a low flying tree at 50mph, but was not difficult to repair
once we stopped...

2527. Newbie Dipole Questions

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-04 17:18:10 UTC
From: newbie
Message-ID: <3a7d88c5.12511499@news.accessnv.com>
Source record: 170901

A few dipole questions if I may.

I want to make a 20 meter dipole. Everything I have read said it should be 1/2 wavelength (33 ft) above the ground for the figure 8 directivity pattern or else it will be omnidirectional. What if the roof of my house is 15 feet high at the peak, does that mean I would install the dipole 18 feet above the roof? Or does the roof qualify as the ground so the dipole would still have to be 33 ft above the roof?

Another question. Would a dipole mounted on the roof, say 3 or 4 feet above the roof, out perform a dipole running over my yard (about 15 feet off the ground but running parallel between the house and a steep hill with about 5 feet between the antenna and house and the antenna and the hill (basicallly a 10 foot wide "alley" between the house and hill and the antenna running down the middle).

If I feed a dipole with 50 ohm coax and the feed point of a dipole is 75 ohms, don't I already have a 2:1 SWR ratio even exactly at resonance? Do I need a 1:1.5 balun? Some baluns I have seen look big as if you might need a support just to hold up the balun at the center of the antenna. My transmission line would run out of a slightly open window. The edges of the window, as well as the window frame, are made of aluminum so I guess twinlead or ladder line would be affected by the metal content and I don't have an antenna tuner anyway.

Last question, how far should the ends of the dipole be from the "masts" that are holding them up? When I try a rope to the end insulators, what is the minimum spacing between the end insulators and the mast I try the rope to? Does it make a difference whether the masts are a tree or a metal pipe? Thanks for any help.

I haven't heard any no-code techs assert that they are accomplished CW
operators. And CW remains as the most simple, basic, easily implemented
radiocommunications mode.
Don't blame it on me, Cecil, It was fact long before I came along.

2529. Loop antenna results

Source record: 170903

Finally finished construction of my small transmitting loop antenna. Using a vacuum variable cap 450 pf @ 7.5KV allows me to tune 40-10m. Antenna will actually tune down to 4.8 MHz. At resonance SWR is unmeasureable on my TS450S. First contact running 50 watts was a fellow in Buffalo (about 350 miles) on 40m with a 57 report. Not bad considering the antenna was still in my basement about 3 feet below ground. If anyone is interested in constructing one themselves I can provide pictures and a list of the materials I used in building mine. My total cost including the cap (I got a great deal, thanks John!) was about $150 Canadian, compared with the MFJ loops which sell for over $650 here! Maybe now I can enjoy some good HF.

73,

Max

richardharrison@webtv.net (Richard Harrison) writes:

>N2EY wrote:
>"The FCC didn`t think so for the first 25 years of the novice."
>
>Then was then. Now is now.

You've taken the above statement completely out of context.

>The FCC now has a no-code entrance to the ham
>bands.

Yup - for ten years now.

After it was enacted, there was a short flurry of newcomers - then the number of new licensees went back to the pre-1991 levels. Turned out the code test WASN'T a major reason for slow growth.

>It doesn`t relax the obstacles to ham radio enough.

What's left? The Tech written was made even easier in the last restructuring. I took a couple of test exams, and didn't even encounter a single Ohm's Law problem. It's basically an extremely basic test on the regs and safety. Easier than the old Novice written.

Do not be fooled by the increased rate of growth of the Tech numbers since April 2000. The FCC is renewing Tech Pluses as Techs, so the growth is composed of both new licensees and old renewals from Tech Plus.

>There should be no code requirement for any ham band.

I disagree. It's all opinions, anyway. The treaty prevents any further code test reduction.

The best compromise I've seen is to have Morse-only subbands. in each of the HF/MF ham bands. Morse test for those subbands only. Those who want to use Morse would need take the test - everybody else doesn't.
>
>Morse code is more recent than the Latin language, but it is less alive
>and has less value.

No. That's just not true. Now you are talking against the MODE, not the TEST.

How many humans use Latin in their daily communications? Very very few. How many use Morse? Hundreds of thousands, at least. Morse is alive and well on the ham bands.

In fact, that's your best argument against a Morse test. Even though hams are not required to use Morse, hundreds of thousands do so BY CHOICE. No reason to run down the mode like you do.

> Latin is recorded in ancient writings worth
>interpretation and preservation.

Sure. That makes it a language of the past. It's not being used today. How do I say "The double conversion superheterodyne receiver has a crystal filter in the 45 MHz first IF and a DSP-based selectivity/demodulation system in the 455 kHz second IF" in Latin?

>There isn`t much of that in Morse.

Because it's not a "language" in the same sense as Latin.

How many radio stations transmit any Latin? How many use Latin as the primary mode, or even as the only one? Extremely few- probably none. But there are plenty of stations that use Morse that way.

Your comparison works against you. Latin is dead, Morse is alive.
>
>Why learn Morse? Only to fill some arbitrary regulatory requirement.

Wrong again. Totally wrong. Why such antagonism for such a wonderful mode?

The license is one reason. But there are many, many others. Here's a short list:

- Lots of folks on the air using it
- Simple equipment can give excellent results
- Gets through when many other modes don't.
- A different experience than voice or keyboard
- Lots of fun once you have some skill
>
>You can learn and practice Morse for fun. It hurts nobody.

Then why do you run it down and condemn it in practically every post? You'd think the USE of the mode was akin to some sort of vice.

>But require it?

Use is not required. Only a very basic test. That test will almost certainly disappear after the treaty changes.

>Morse is already phased out of every pursuit except amusement.

Not true! Simply not true.

It's use is highly limited outside of ham radio, of course. But why is what OTHERS do such a concern about what hams do? Other services have largely phased out SSB, too. Any other services use 60 wp Baudot RTTY? SSTV? EME?

>Even last resort claims are more fancy than fact.

Tell that to the crew of MV Oak.
>

>The idea that Morse enobles doesn`t prove that the same effort spent on
>something else wouldn`t be more enobling.

"Enobling"? What are you talking about?

>It would very likely be more

Like what?
>
>Numbers count!
>
>With a large market for ham gear, you might benefit from lower unit
>pricing. With a lot more hams, congress would pay more attention to what
>hams wanted.

Maybe. Or maybe not. They pay the most attention to the big corporations with
the new whiz-bang "wireless technologies" and the big bucks.

>Bigger is better.

Quality overrides quantity.

>Minimum requirements is the way to grow.

Then why hasn't it worked?

The "minimum requirements" idea has already been tried. It's called CB. The result has been chaos. The FCC has been trying to control and clean up CB since the early '60s, with little success. Have CB's enormous numbers gotten them a better service? NO!!

The latest reductions in license requirements have been motivated in part by the hope at the FCC that some of the CB and freeband folks will get ham licenses and clean up their acts. Maybe it will work, maybe it won't. But if you want to see what a "fishing license" type of radio service is like, just tune around 27 MHz. Is that what you want ham radio to become? I don't.

Dick Carroll wrote (concerning a c-w licensing requirement): "---only to 1.) Learn to use a basic communications mode, and 2.) To qualify for an HF amateur radio license so long as ---."

CW may be basic, but it is no prerequisite to any other mode.

CW has been defended as essential to emergency communications, which is mistakenly claimed as a mandate of amateur radio.

Amateur radio is a hobby.

Amateurs set up emergency and public service groups in which they can put their communications gear to good use. It`s all voluntary. Cell phone users can do the same. If the cell phones fail, there are satellite phone and internet connections.There are more do-gooders with cell phones than radio amateurs. They are welcomed volunteers with the Red Cross, etc..

Amateur emergency help may be welcome, but it is seldom essential.

Newsflash: Amateurs don`t have to earn spectrum for their radio hobby through good deeds. They have access rights simply by getting an FCC license. Just as commerce and industry are worthy and have rights, so do individuals, for their life, liberty, and pursuit of happiness.

Dick Carroll is dwelling upon long gone times and conditions before there were modern communications.

Best regards, Richard Harrison, KB5WZI

Sorry Cecil,

You are at least 20 years behind the curve with your statement.
Object Orient Programming (OOP - Smalltalk so many years ago) accepts
the tenet of deriving meaning from context through a process known as
operator and function overloading. The central basis of OOP is that
one term may fit many functionalities based upon the context of the
usage.

To go further, OOP also has what is known as "inheritance" where the
meanings of functions are acquired automatically by related functions.

There are more sophisticated languages such as Trilogy, Prolog, or
LISP that push this even further through a mechanism known as
Predicate Calculus. This form of language can figure out meanings
when context is not provided, but must be derived.

newbie,
First, understand that none of this is 'cast in stone', there's
a lot of variation between installations.
As with any antenna, the higher the 'better'. If you can get an
antenna up at a 1/2 wave length, that's great. But if you can't, it
may not make as much difference as you may think.
If there is a lot of wiring, A/C ducting, other metal, in your
attic, the 'roof' may act more like a ground than if there were'nt
any metal there. How do you tell for sure? You don't, try it and
see what happens. Usually, 'ground' is somewhere between 'dirt' and
the roof, and really doesn't make ~that~ much difference.
Would an antenna near a roof out perform an antenna in the clear?
That's another one of those questions that has no definite answer, try
it and see. The antenna in the clear, all other things being equal,
would probably 'work' better. I'd think antenna orientation would
make some difference, but I don't know of any way to predict how much.
The input impedance of a dipole is seldom what the 'book' value
says it is. It'll be somewhere close, but never 'on the money'. The
impedance mismatch you gave wouldn't give you a 2:1 SWR, more like a
1.5:1. Depending on the transmitter, a SWR of 1.5:1 isn't worth
worrying about. If you want to use ladder line, and are worried about
bringing it into the house through a metal frame window, put a spacer
between the window and the jam. I use a 1x6 board, drill holes for
the
ladder line, then shut the window on the board. If you stay 3-4 times
the width of the ladderline from metal, there isn't enough interaction
to make any difference.
Given the choice, the ends of an antenna should be at least 1/4
wave length from any near-by objects. That 1/4 wave length of
distance
is also ~not~ 'cast in stone'. You want the ends as far from 'stuff'
as you can get it, but, if that's 3 feet, then that'll have to do.
If you end up with RFI, or get 'bit' from RF in the shack, try moving
the ends further away from the shack, and/or what ever they are close
to. Changing the dipole's shape from the classic 'flat-top' or
inverted
'V' is okay. The more drastic the change in shape, the more reaction
to that change.
Don't be afraid to experiment with all the variables of erecting
an antenna, that's half the fun of it. There's almost always a
compromise that will 'work' for you... just have to find it!

Basically, what you refer to is an ideal situation, which most of us do not have. Having the antenna on the roof will certainly help, but yes, you will probably get some interaction/pattern skewing from your roof. I would not get real concerned about this, generally speaking. No installation is perfect.

Altitude, is almost always a benefactor, so again, go with the roof.

The feed point of a dipole is ~ 75 ohms if the dipole is stretched out in a straight line, i.e. looks like a "T" with the feed line. However, if the elements are drooped down ~ 120 degrees, it creates the "inverted V" antenna, which also tends to make the feed point impedance closer to 50 ohms. A balun is always a good thing as it tends to minimize radiation from the feedline coax. They do not have to be large, but I know what you mean.

>
> Last question, how far should the ends of the dipole be from the

> the mast I try the rope to? Does it make a difference whether the
> masts are a tree or a metal pipe? Thanks for any help.

This should not really matter much, unless you are using a metal support. However, if you are simply tying off to a tree, wooden mast, or perhaps the fence, it really does not matter. On the other hand, you do want to keep any part of the antenna itself well out of reach from children, and probably most adults, for safety. There can be quite a bit of RF voltage on any antenna that is radiating. RF burns really hurt, and tend to take a long time to heal.

Basically, do the math as best you can, cut your dipole to 1/2 wavelength, connect a balun in the center if you have one, get it as high up as reasonably possible, and then enjoy yourself.

You will find that the cutting length becomes somewhat less critical on lower frequencies. I have in a pinch, rough cut a roll of 4 conductor telephone line to an approximate half wave (plus minus a few inches), hooked it to a 1:1 balun, shot a line up into a tree, and had lots of fun on 80/75M all night will no SWR problems on a solid state rig.

It took all of 15 minutes to measure, cut, wrap (no soldering BTW), and then pull the ends up into a couple of trees. Probably did not have the antenna more than 30 ft in the air tops. I got tons of 20, and 40, over reports from coast to coast while running portable in central Wisconsin..

ALWAYS PUT SAFETY FIRST!
This sounds like a broken record of a statement, but people still ignore things like the AC mains from the power company and other potential hazards around the home. Do not assume anything where non-antenna cables or wire are concerned. The telephone line is capable of giving a lethal shock under the right conditions. Don't become a SK!

Otherwise, don't over think dipole antennas, just have fun.

Hi Dean,

This is much different than the Republican Welfare State that doles
out the Public Domain in generous handouts to its shiftless commercial
bed partners that perpetuate the revolving door of economic boom and
bust. These Welfare Whores still travel by Mercedes and Cadillac to
the Welfare Office to claim that their "rights" be undisturbed by the
people who paid for them.

The owners of this Commonwealth (yeah, that of the people and by the
people - not the corporation) seek to retain their own rights and
property and are hassled by every right-wing panhandler mumbling he
only wants spare change to cover his cheap drug habit.

The left wingers want to give it away, the right wingers would be
satisfied with a bottle of Muscatel.

Just say no. A pox on both their houses!

Source record: 170915

Roy:

Thanks for that detailed explanation of the current balun. I agree with all you have shared with us, however there are different ways of viewing things and so...

Let me feed back what I think you said...

I believe another way of stating what you wrote is that the current balun is actually an inductive reactance choke placed in the common mode path so that it "blocks" common mode currents.

Thus the "current balun" a.k.a. "common mode choke" actually enforces the current "balance" on the counter-directional transmission line paths for the go and return currents by inserting a high impedance in series with them and enforcing approximately zero current flow on the third path, the parallel combination of the go and return paths. [the "sneak" path a.k.a. common mode path].

A physcial model for this common mode choke is simply a pair of coupled coils wound "two in hand" with each physically separate winding connected, for conduction currents, in series with the paths making up the transmission line, and only the mutual magnetic coupling, and stray capacitances, connecting the two sides. Such a pair of coils will have a small primary Lp and a small secondary Ls leakage inductance a mutual inductance M, and a coupling factor k, from which one can calculate the "large" magnetizing inductance Lm. In addition there will be 'stray" interwinding capacitance which will contain some imbalance as measured from one side to the other with opposite ends of windings grounded...

i..e. all the same stuff as any other transformer... and so far... the current balun is no different than the conventional transformer, no?

The ONLY difference that I can see between a convention transformer and the current balun is in the "connection" to the transmission line... otherwise they seem to be the same to me.

For any transformer we always strive to get (Lp+Ls)/Lm as small as possible, no? What?

For the current balun, it is only the somewhat different or unconventional "connection" in the transmission line of this "two in hand" wound transformer which then causes the large magnetizing inductance to appear in series with each conductor on the transmission line, while the two smaller leakage inductances and the interwinding capacitances, now actually cross couple the two conductors in the differential transmission line paths. [Sort of the opposite situation from conventional transformer usage where

the magnetizing inductance appears across rather than through and vice versa for the leakage inductances and interwinding capacitances.]

Now the high impedance, or more accurately the high inductive reactance, of the magnetizing inductance of the "two in hand" current balun blocks the common mode currents on the transmission line, while the imbalance of the the two leakage inductances together with any imbalance in distributed capacitance, and/or winding resistance, between the windings will tend to let common modes sneak by again.

And so... I believe that the ratio of the magnetizing to the leakage inductance for any two winding transformer is a quantitative measure of the "ideality" of the balun in either case. Either for a voltage balun or for a current balun. i.e. one wants the ratio of the magnetizing inductance to the leakage inductance of the transformer to be as high as possible, whether or not it is connected as a current balun or as a voltage balun.

It just so happens that... winding a two winding transformer by taking two conductors and winding them "two in hand" instead of say sequentially or overlapping them, etc.. is a very good way of getting the physical symmetry that creates equal and small Ls and Lp, while simultaneously maximizing k and Lm! This will make a good current balun or a good voltage balun, it doesn't matter.

Winding a transformer with two wires "in hand" is a good thing to do, nothing more, nothing less. Just a way of making a great transformer!

A good current balun should make an equally good voltage balun and vice versa.

Given that the best manufacturing process for either the current or voltage balun is the same, i.e. wind using the "two in hand" technique, then the only diffrerence between the two is in the way you hook them up (application), not in the way you wind them (construction).

Either the current or voltage balun should be made as close to perfect as you can make em.

Then after you have a well made, nearly ideal, ttransformer, you can decide how you wish to hook the device up, i.e. to reduce common mode transmission line currents by "blocking" [read current mode] or by "forcing" [read voltage mode].

In some applications one hook up is better than the other and vice versa.

Now if an ideal transformer has:

(a) Infinite magnetizing inductance Lm
(b) Zero leakage inductances.
(c) Zero interwinding capacitances

ignoring winding resistance, then...

a "real" transformer has finite magnetizing inductance and non zero leakage
and interwinding capacitances.

Then in balun construction, one should strive to get Lm/(Lp+Ls) as high as
possible, while minimizing the parasitic capacitance unbalances.

I wonder which is the dominant factor in causing performance degradation in
current mode baluns??

Low Lm/(Lp+Ls) ratio or parasitic/stray inter-winding capacitance unbalance?

Thoughts comments?

Yes, more like 'allum-minny-um'. I spell 'colour' and 'labour' with a
'u', and there are two Ls in 'traveller'. I pronounce 'solder' as it is
spelt (not 'sodder').
As for wigs, I think that they are really mainly used for ceremonial
appearences (I presume you are talking legal).
However, I often prefer the American spelling of 'analyzer' and similar
words (with a 'z').

Hi Bob--

1. Height: If you can get the dipole up 30-40 feet AGL, that's pretty ideal for good DX on 20 meters. However, go too high (say around 60 feet) or too low (say 15-25 feet), and the low-angle pattern you need for working DX will probably drop off.

2. SWR: A 75 ohm antenna yields 1.5:1 in a 50-ohm system, not worth bothering with. However, if you configure the antenna as an inverted "V", this will lower it impedance--bringing it closer to 50 ohms.

3. Pole Material: You can use a metal pole--the coupling between the horizontal (or inverted V) antenna and vertical pole will be minimal. Just don't let either leg of the antenna contact and enegize it!

4. Balun: Use one! However, rather than spending big bucks to buy one, just wind up a few feet of coax at the feedpoint and tape it together. This'll work just as well.

Good luck with it!

Yes. All you need to do is place your rig on the ground, run radial
wires out from it in the yard, and connect it via a 1/4 wavelength
feedline to the antenna. Makes a great setup for an outdoor picnic.

Indeed it can, as long as you're aware of the impedance level you're dealing with and design the transformer accordingly.

For beach operating, a kite antenna is ideal. Put the kite up high enough
for stability (doesn't have to be very high on the beach, the wind is
smooth). Attach your antenna to the line at a point that will elevate it to
the desired altitude and operate. Using a good kite, it will fly unattended
all day and you won't have to worry about poles. I have done this a lot.
Works great.

You sure??? I remember in the early 70's a friend of mine took the advanced when in jr.hi school and he had to draw a few circuits if I remember right. I remember him talking about them. This was about 1971 or so. The majority of the questions were multiple choice though. Seems he only had to draw out one or two circuits on the whole test. MK

In the internet context, you wouldn't hear it unless you read aloud. However, such brain farts are certainly visible.

: Clearly "typo" is probably more appropriate for application to the USENET NG
: medium.

To me, typos consist of such things as - transposing letters, dropping or adding letters in words that are normally spelled correctly, adding an occasional random character, dropping a word or typing it twice in a row.

A brain fart is when you know better, but think the wrong thing when you type. My "300 ohm" mistake was a brain fart. I know that the impedance is much closer to 3000 - but I thought 300, as in the case of a folded dipole.

In article <bjiq7t4i3gjt9r8fhu6f2kjen5pr21oaqi@4ax.com>, Bill Turner <w7ti@jps.net> writes:

>The RSGB is a single entity, therefore, the RSGB has, not RSGB have.

Actually, the RSGB is NOT a single entity - it's a "society". Americans tend to use the singular, but the correct way is to use the plural. "The committee have decided", for example.

--

It's and its are so easy to tell apart - simply try to use "it is" there and see what happens. If it works, use the apostrophe version, if not , use the other. Simple.

--

73 is already plural. Adding an s or 's makes no sense. "Best regardss"? Best regards's"?

You didn't say "accomplished CW operator", Dick, you said "accomplished ham". That's a near-infinite conceptual difference. Read your above statement and you will be forced to admit that you think a nocode tech cannot possibly be an "accomplished ham" even if he/she is far superior to you in every respect besides Morse code. Your delusions of grandeur are showing. Why don't you find something different to base your sagging self esteem on besides Morse code? Are you a failure at everything else?

The lousy grammar used by many of today's generation seems to me to be the result of the lack of time spent in primary and elementary school spent on drilling in the rules of language. Most of the common mistakes I see are caused by the lack of the application of those rules.

Could it be that time formerly dedicated in the third and fourth grades to grammar, spelling and handwriting is now spent teaching keyboarding, drug awareness and dealing with social problems?
Not to mention the lack of time allotted for teachers to apply the sharp red pencil to student essays, when the student to teacher ratio exceeds thirty to one?

Richard Harrison wrote:

> CW may be basic, but it is no prerequisite to any other mode.

Of course not, it is prerequisite unto itself- you can't use it if you don't know how.

>
> CW has been defended as essential to emergency communications,

No, it has not- it has been shown to be the most basic of radio communications modes, still very effective even though it is quite ancient by comparison to the flashy efficient new modes that require much more hardware overhead and support.

> which is
> mistakenly claimed as a mandate of amateur radio.

You can ignore the history of the amateur radio service but your attitude cannot change it.

>
> Amateur radio is a hobby.

Sure it is. But unlike almost all other hobbies, it is something much more. No stamp or coin collector will ever find himself in the position to use his hobby to perform critical public services. Most hams will never see the time when they are called to do so, either. So in your opinion no ham need ever prepare nor expect such a thing to happen nowadays, what with cell phones and satellites. Your understanding of the frailties of modern communications belies the level of your education and experience. You simply should know better than that. For some strange reason a number of engineer-hams suffer from that very deficiency. Oddly, many are no-coders, also.

> Amateurs set up emergency and public service groups in which they can
> put their communications gear to good use. It`s all voluntary. Cell
> phone users can do the same. If the cell phones fail, there are
> satellite phone and internet connections. There are more do-gooders with
> cell phones than radio amateurs. They are welcomed volunteers with the
> Red Cross, etc..

This paragraph only shows your lack of expressed knowledge of reality of life in the world of communications. Only ham radio incorporates such a diversified widespread cadre of operator/stations as to be capable of detaching itself from the gridded infrastructure to the extent that it

can function on its own without dependence on such things as power grids, networking schemes, or both. When the lights go out for long periods, or some natural calamity comes, the telephone network clogs- did you ever get the "all circuits are busy" notice? Don't even mention the cellphone network. It was never designed to handle large percentages of its subscribers and saturates straight away. Satellite phones? You mean IRIDIUM? Globalstar? Yeah, right! Not much help there. ALL public safety comms are in instant overload when the ship hits the sand, been there and done that. That leaves FRS and CB. Real organization and true communications capability there, for sure. NOT!

So you go right on blithely assuming that all is well, and your world is secure. If you lived in California you would have assumed, until a couple weeks ago, that your lights were certain to stay on at will, too, and there would always be a working traffic signal at each intersection on the glutted streets and highways.
Modern communications systems are far more fragile and vulnerable than you evidently can imagine. Ever hear of the "Digital Pearl Harbor"? Everything out there is ran by computer these days. That makes everything vulnerable to the hackers. Microsoft itself is not secure. What next? It won't necesarily be a natural disaster that takes modern comms down.
A few years ago in a fairly large town not far away a fire in the central telephone office put the city off all telephone service for days. Meanwhile, the local ham radio 2meter repeater filled in nicely for local critical communcations. Later the telephone company awarded the ham radio club repeater space on its mountaintop site in appreciation of their help. Not a big deal, and rare, but just one more example. So many of you code bashers are so eager to do away with all but the "hobby" aspect of ham radio. Why?

> Amateur emergency help may be welcome, but it is seldom essential.

And when it is essential it is far more than welcome. It is - well, essential.

> Newsflash: Amateurs don`t have to earn spectrum for their radio hobby
> through good deeds. They have access rights simply by getting an FCC
> license.

Ah, now we get down to it. "I have a right". Sure you do. One which can be withdrawn at the stroke of a pen "In the public interest, convenience and necessity".
Comes the time when amateur radio is seen by officialdom as nothing but a burdensome klaven of simple hobbyists and troublesome misfits, a significant portion of whom really don't care, and that pen stroke becomes reality. It has been made perfectly clear that the slide in the direction of worthlessness as a service has been in progress within the Amateur Radio Service for decades.
The instant brouhaha merely serves to grease the skids.

> Just as commerce and industry are worthy and have rights, so do
> individuals, for their life, liberty, and pursuit of happiness.

Which does NOT include transmitting access to any part of the radio spectrum for recreational purposes. There is a "basis and purpose" for the amateur radio service in the FCC rules. You really should read it sometime.

> Dick Carroll is dwelling upon long gone times and conditions before

And thus, each government which signed the treaty was left to their own definitions of "proficient". Some decided that 12wpm was the minimum level of proficiency. Others decided 5wpm. Not one, anywhere, decided on any speed below 5wpm. The USA decided on 5wpm instead of some higher speed, preferring to allow those who urged themselves on to higher speeds to gain additional operating privileges by so doing.
You guys are lucky. Instead you feel offended. Pity.

Any ham who cannot perform minimally at Morse code, the most basic
radio communications mode, is inherently unqualified at basic radio
communications.
When one is unqualified at the basics, how can he claim to be fully
accomplished?

> Your delusions of grandeur are showing.

No, YOUR delusions of grandeur are trying to show, but they aren't
making much headway because you know that fact is fact, and you are on
the wrong side of the argument.

> Why
> don't you find something different to base your sagging self esteem on

You really don't get it at all, it's plain to see. This isn't about
me, nor you, except that you would join them for reasons of your own.
It's about those who prefer to ignore reality. That is: The most basic
radio communications mode is radiotelegraphy. Find one that you can show
to be more basic and we'll look again. I won't stay up late waiting.

Play with the words as you will Cecil. It seems to be one of your favorite pastimes when you don't know exactly how to respond to something you don't like. It really is quite simple. We are a rule based society whether you approve of that or not. Acquiring what you want through effort directed toward fulfilling the requirements under the rules is not called welfare...it is called earning your way.

Earning your way unfortunately is rapidly becoming outdated in today's politically correct society. We should not require anything of anyone if the process could possibly result in their not acquiring whatever they want. Discrimination, favoritism, being deprived of something that belongs to all people...all are buzz words used in the process of lowering standards throughout all of society.

The freebanders want no rules in place. Everyone who wants a ham ticket, gets one. No rules equals chaos, ie, citizens band.

How can you be fully accomplished without experience at Spark Gap?
Spark Gap is certainly one of the original "basics". Your delusions
of grandeur about Morse code are worrisome, Dick. Aren't you good
at anything else in the world? Hanging all your self esteem on an
outdated governmental requirement is psychologically dangerous.

I'm going to jump in here, Jason, but I'll be first to admit that others can undoubtedly give you a more authoritative answer.

You didn't say where you were going to mount this antenna. But, if it will be above ground, I think you are making a simple job way too complicated. My "Antenna Handbook" by Bill Orr and Stuart Cowan has a great graph showing that the number of radials needed is dependent on the height of the antenna base above ground. For example, at ground level it is ideally 120 radials; at 0.1 wavelengths it's 60; at 0.2 it 10 radials and at 0.5 it's 4 radials.

I took this to heart when I made my 20m ground plane out of scrape aluminum tubing and mounted it on my roof peak 27 feet up. With five 1/4 wave radials it works great. I can't think of a single CQ I haven't bagged on the first try (Of course, I usually go after the strong signals so I guess I'm preselecting here.).

Good way to corrode ground systems, There has been more than a few radio
stations that tried the same
then when their signal goes down the toilet the staff or consultant when
checking the radials start to dig
and find green in the soil that use to be radials.

In article <3A7DDC43.388E@wt.net>, Mark Keith <nm5k@wt.net> writes:

>N2EY wrote:
>
>>
>> The written tests became all-multiple-choice in the late 1950s.
>>
>> 73 de Jim, N2EY
>
>You sure???

Absolutely. I have several License Manuals - earliest is 1948. The 1953 and earlier editions mention having to draw schematics and block diagrams. The 1962 edition specifically mentions no schematic drawing - all multiple choice. The ARRL License Manual sample questions were actually reprints of the FCC-issued sample questions/study guides. The info in the LMs was derived directly from the FCC stuff.

> I remember in the early 70's a friend of mine took the
>advanced when in jr.hi school and he had to draw a few circuits if I
>remember right. I remember him talking about them. This was about 1971
>or so.

He was pulling your leg.

I took the Novice in 1967 (age 13, 7th grade) and the Tech and Advanced in 1968 (age 14, in the summer between 7th and 8th grade). All multiple choice - no place to draw schematics if you wanted to!

What they DID do was to show a schematic of, say, a crystal oscillator and ask you what it was. They also showed an almost-complete schematic with various points identified and asked you what was needed to complete it.

Like this:

"The circuit shown is a triode RF power amplifier. To neutralize this circuit, which of the following should be done?

1) connect a resistor from A to B
2) connect a capacitor equal to Cgp from B to C
3) connect a capacitor equal to Cgp from C to E
4) connect an RF choke from D to A...

(you get the idea)

Same thing for block diagrams.

I took the Extra in the sumer of 1970 - had to wait two years back then.

>The majority of the questions were multiple choice though.

By 1961, all of them were. There were two main reasons for this:

1) Less work for the FCC to mark them
2) More objective testing - no interpretation needed. Either you picked the right answer or you didn't.

>Seems
>he only had to draw out one or two circuits on the whole test.

He was pulling your leg - the schematic drawing stuff was gone when he was still in diapers. I know - I was there before him and took all of the tests before he did.

None of the old tests were particularly "hard" IF you knew the material. I knew of some 12 year old Extras in 1970 or so - that means they had to get their Generals by age 10. I was an old timer by comparison, getting it at 16.

The big difference was that since you did not know what the exact Q&A were, nor how they would be distributed, most hams went in overprepared. For example, a prosepective ham knew there would be Ohm's Law questions, but not how many or what they would look like. So he/she learned Ohm's Law and related stuff backwards, forwards and upside-down, to be ready for any possibility. Same for lots of other stuff.

That's not necessary today.

I agree with you Rory, except for the last part. I can't remember
ever being in a class with less than 30 students, especially in
college. Neither were my children. I think other factors are at work
here which takes away from the time available to teach.

A radio station that use to be near Washington's Crossing, Pa had top
loaded 5/8 wave towers
with driving impedance's that was next to impossible like 0.6 -J 800 ohms
that was a challenge
at best. A OIB-1 rated 10 KW smoked with 500 watts applied, at monitoring
points you could
watch signal levels change with someone just walking into the doghouse! The
other 3 towers
were better but not by much, Truly a installation from hell.

First the handheld is likely tuned for the rubber duck, you would have to
retune the output stage
to match your new antenna, second you have lossy feedline.

Cowboy,
The Imax 2000 will cover the lower part of 10meters 28.300 to 28.500 and
11meters OK or 12meters & 11 meters but in order to do all three you would
have to use at least 100ft of coax or a tuner to cover all three bands at
the same time. 73s Oldtimer

Dick Carroll wrote:
"Only ham radio incorporates such a diversified widespread cadre of operator/stations as to be capable of detaching itself from the gridded infrastructure to the extent that it can function on its own without dependence on such things as power grids, networking schemes or both."

You enjoy lower insurance rates because your fire and police departments have hardened radio systems which can be independent of the local telephone and power systems.

Come on! The commercial networks are extremely tolerant of disruption. Failure triggers instant rerouting to get the message through.

In dire continuing problem spots, there are available elaborate police and sheriff communications vans with everything needed for fairly long-term operations. These are always ready to roll. There are National Guard units with communications gear and operators awaiting a governor`s orders to be used where needed. The armed forces are well equiped and awaiting federal orders. Then, there is a multitude of private industrial and commercial communications networks with independent power and divertable capacity. Almost any large TV station can dispatch a capable satellite remote across the street or around the world. Or they can send a helicopter with a minicam.

All hams could be ordered off the air and be hardly missed for emergency communications. All the police, military, industrial, commercial, broadcast, and other professional emergency communications are operated by disciplined professionals using professional equipment and are more reliable than the amateur community.

You can have all the heroic dreams you like, but it doesn`t square with reality.

What ham radio does well is provide communications for marathons, fun runs, bicycle tours, etc. which are promoted by charities as fund-raisers. Free communications for these is not in the charter of the other organizations.

Best regards, Richard Harrison., KB5WZI

You are no better in guessing political proclivities than you are at determining fairness with respect to rewarding initiative, work ethic and earning one's way. It is also obvious you pay little, if indeed any, attention to what amounts to a total lack of rules and enforcement within the CB arena. Whether they are called freebander or no-coder, the end result is identical. They want a ticket to ride without earning it.

Yes, at the base of a vertical that could help a lot.
>
> As I understand it, the ideal ground plane for a vertical antenna is an
> infinitely large conductive plane.

You pretty much answered your own question with that statement. A solid
sheet or plate would be better than wires with gaps in between them. The
solid plate is total saturation of the radials. Can't do any better than
that. This means the most at the base of the antenna. I would think the
farther away , the less critical. MK

I'd have to ask him. I thought he had to draw out a couple of
oscillators or something along those lines, but I may have mistaken that
for what you mentioned. I didn't get a ticket until 1977. I learned all
I needed to get the novice in 1971 "8th grade", but then just put it
off for some reason. I was also busy with band and running track at that
time. I finally took the test in 77 when I was 20. As I liked the code,
I didn't mind being a novice. I stayed a novice until 84, when I
upgraded to general. I probably would still be a general except they
started the "buy a call sign" thing, and I decided to dump my old call
which I wasn't overly fond of. Thats the only reason I upgraded. I took
the advanced one week , and the extra a couple of weeks later. Didn't
stay advanced very long at all. I blinked and it was gone. That was in
96 I guess. At this time, I have 4 paper tickets that all have valid
dates. Three for WD5CJL, and one for NM5K. Of course only the last is
"really" any good now. I have a general, advanced, and two extras. :-/

Gary,

I'm not so sure that you are correct with your assertion of Eastings preceding Northings. I accept that this applies when using map grid references such as Ordnance Survey, but when using latitude and longitude they are expressed in that order.i.e. Degrees (and their subdivisions depending on the system used) North (or South) followed by West (or East).

The other nice thing about experimenting with wire is that you can make it into one kind of antenna, then tear it down and make it into another. Dipole to inverted-V is obvious. But, you could also make it into a vertical (for the higher bands) if you have a tree or other vertical support. Ground mounted verticals are a pain, though, since you usually need a zillion radials.

True. What they used to do was make a ring of aluminum
with 4 "spokes" to couple it to the radiator. This way the
wind would blow thru it while mobile.

BTW - Don't forget that Art Bell returns tonite to late night radio.

Thanks Bob, I find it strange that people complain about proper
English and want to replace it with ham jargon. :-)

Dunno,
but my father once revived person who was hit by lightning and pronounced dead, by quickly burrying the body in the ground (face sticking out). The person came back to life after a while, appears that charge was "sucked" by the earth and function of the organs was restored (body wasn't burned).
Not sure if this would work after so long, but might be worth trying, can't hurt. Doctors don't know everything.
Strange things happen like blind woman got hit in the head and started seeing again (recently in the news).

"The New York City Marathon is a "fund-raiser"?"

It is illegal to use ham radio in "for-profit" activities.

For-profit companies can use their commercial radios for non-profit activities. It works out that way unintentionally for some. For others, their extensive radio systems are often intentionally used for the emergency non-profit greater good of the community. Our company about 40 years ago installed ham radios around the USA for cooperation with hams in emergency situations. Don`t recall them ever being used for relief, only for amusement of some employees who were hams. The FCC would likely frown upon companies using their commercial radio channels to support local "Fun-Runs".

Where can I obtain a crystal ball like you have? Where are the hoards
of CBers and freebanders who were supposed to invade the ARS after
April 15?

> It is also obvious you pay little, if indeed any,
> attention to what amounts to a total lack of rules and enforcement within
> the CB arena.

CBers are untested, unlicensed, and unsupervised. They bear no resemblance
to the ARS.

> Whether they are called freebander or no-coder, the end
> result is identical. They want a ticket to ride without earning it.

Make the ARS requirements a PhD in electronics and 100wpm code. The
freebanders will still be there. The no-coders would disappear. Freebanders
are unlicensed criminals. No-coders are licensed amateur radio operators.
There is no comparison. P.S. (Prozac would probably reduce your paranoid
delusions. :-)

No-coders and freebanders are the recipients of the welfare state of amateur radio because that is what they have made it. They now outnumber those who believe in the old fashion method of acquiring what you want by earning it. When you are outvoted, you loose. I don't like it but I accept it because that is the way things work.

I suggest you might want to consider whether you could derive benefit from using the Prozac that you prescribed for myself. It does seem to me that you are spending an inordinate amount of time worrying about, and attempting to define, what you refer to as delusions of grandeur; sagging self esteem; the political leanings and the alter egos of, many of those posting to the group.

2613. SW antenna basics for dummies please

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-05 17:20:39 UTC
From: Jim <arnoldjimjim@hotmail.com>
Message-ID: <3A7EE153.FA13502A@hotmail.com>
Source record: 170787
Cross-posted to: rec.radio.amateur.antenna,rec.radio.shortwave

I've read through SW antenna discussions and it's all way way beyond me. Web pages all seem over my head too. Can someone point me to an "antennas for dummies" (or beginners) web page or book please. Maybe I also need a reference about basic radio theory. Perhaps there is a FAQ posting I haven't seen. (I had a good reference 30 years ago called "Instructions for Radio Construction", but alas it went with the wonderful tube radios my parents gave away when I was 20 (Normende Elektra, Grundig, and FM transmitter I built and a couple of crystal sets. I working on relieving the pain now).

I live in Saskatoon, Saskatchewan, Canada, and what I gather (sort of) is a passive outdoor antenna is likely best. I am completely lost as to why wire must be insulated, why/whether lengths and gauge matter, how the plug-ins in the side of my Sangean ATS 909 and Grundig 300PE are set up. I have the plug passive antennas these radios came with.

The last time I had a big antenna was 1968 or 70 and I just strung 120 feet of wire out the window around the second storey of my childhood home, stuffing it under the shingles and chucking it over to the neighbour's roof and doing the same thing there, clipping it to the telescope antennas with an alligator clip. What will I gain by something more complex? Does north/south/east/west orientation around a roof make a difference. The active/passive antenna thing also has me completely boggled. I am looking to extend the SW hours into the daytime more (I can only get BBC fading in and out, USA audio-evangelists and lots of Spanish, though I heard Russia and got Kuwait yesterday), and I am a long way from signals here (-7 hours UTC), 600 miles north of USA border. Any simple instructions and why I would choose this or that would be gratefully accepted.

Thanks, Jim Arnold

He was probably pulling your leg or maybe he remembered it that way.
But the FCC ham tests were all multiple-choice before 1961 - at least
ten years before he took his.

I can photocopy the old LMs and QST articles if proof is needed.

> I didn't get a ticket until 1977. I learned all
> I needed to get the novice in 1971 "8th grade", but then just put it

Back then you had two years to upgrade or lose it. Some hams (then and
now) would get the license with no thought about how they were going to
get on the air. By the time they had acquired a receiver, transmitter,
key, T/R system and antenna, precious months had been lost. So it may
have been a wise choice.

> I was also busy with band and running track at that

> "really" any good now. I have a general, advanced, and two extras. :-
/

What a neat story! I was sort of the opposite - couldn't wait to get on
the air, then to upgrade.

Got the Novice in 67 and went for the General in 68, but the FCC examiner couldn't read my writing so I muffed 13 per the first time. (That was back when you got 5 minutes of code and at the end the examiner pulled the paper - no time to go back and fix anything.) But there were 25 consecutive characters legible, so they let me take the General written and I walked out with a Tech - held both Tech and Novice at the same time, and which callsign I used depended on the band used.

Went home and taught myself how to block print so there would be no confusion over longhand. 35 days after the first try (the next possible session after the 30 day wait to retest) I passed 13 wpm - and the examiner said "why not try the Advanced?". One did not say no to The Man back then - certainly not if you were 14 years old. So I tried and passed and walked out an Advanced.

Back then you could not use the new privileges until the actual license arrived - which took 6-8 weeks. I spent the time getting a VFO set up so I could move out of the Novice band. When it came (fall of 68) I had a few weeks of full privileges, then lost them because "Incentive Licensing" took effect.

You know the rest of that story - got 'em back in 1970. Got this callsign in 1977 when I moved to WNY and kept it when I moved back to EPA. Back then you couldn't buy a callsign (legally, anyway) - you just took the next one on the pile.

The government cannot control criminal behaviour on RF any better than
it can keep guns out of the hands of criminals. Nocode techs are just as
much a legal part of the ARS as you are. Freebanders are criminals and
don't care one iota about license requirements. There is absolutely no
relationship between unlicensed freebanders and licensed nocode techs.
Your Chicken Little attitude needs a reality check.

The K10 has different windings in the coil. I think I had to cut off about
8 to 10 inches on my K40. I never said low SWR means good antenna or low
loss or whatever. Low SWR means I was not hurting or cutting back my rig.
Usually on a short or loaded antenna, wide band width and low SWR acrossed
it means poorer performance. That is what I see with my K-40 compared to a
Huster, SGC, screwdriver, or 102" whip with Icom AH-4 coupler.

Well, you can make this highly overly-complicated, or simple. There's
just not a hell of a lot that is critical in a receiving antenna for
shortwave (transmitting antennas are much more complicated).

Just string up the longest piece of wire you can. If you can get it
outdoors, that's great. If you can keep it away from the house, where
you might pick up interference from household gadgets, and away from
powerlines, where you can pick up powerline buzz, so much the better.
It doesn't really matter much how long the wire is. Just make it as
long as you can and don't worry about it. The higher the better. The
more in the clear, the better.

Another thing you can do, if you wish, is contact stores that sell swl
stuff, tell them you're a total doofus on antennas, and do they have
any basic swl-ing books that explain this stuff. The stores below are
good places to start.

Good luck!

Good antenna. Just make sure you have the room for radials. Works better
if elevated. Works good with at least 2, preferably 4 or more radials on
lowest band, in your case at least 33 feet long or so in an X patern from
the base of the antenna. You need coax also. I would go with a 80 meter
dipole and feed it with ladder line to cover all bands and you can get a MFJ
tuner for about $150.00 to flatten the dipole. Works on 6 meters too.
Spend a bit of money on the tuner now because you can play with a lot of
antennas you can build cheap from wire. You can't do that with the 4BTV.

I tried an attic antenna once, and every time I transmitted, the whole
damned house went crazy. My "surf"-noise bedside gadget let out loud
snarls whenever the transmitter was keyed; lamps lit up; it was funny.

You might just go around the house and unplug appliances and gadgets
individually to see where the noise is coming from. Maybe you can
solve the problem with ferrite split beads on the AC lines. Ferrites
might also help the fire alarm. Maybe...

Bob

Well, I'm not completely positive, which is why I asked the question. But
I did a web search for kite antenna, and most of them said that one must be
very careful about providing a path for static discharge so as not to
damage the rig or the operator.

Something about there being no ground mounted physical support in a kite
antenna, as there is with any other kind of antenna, and that the normal
support distorts the earth's EM field enough to not have this problem.

I dunno. Like I said, that's why I'm asking here.

Hi Cecil,

I can only imagine that by "context free language" you are speaking
about DOS Batch files. I say this because since the introduction of
Win95, I would speculate that nearly every application has been
developed in an OOP language. There is still VisualBasic out there,
and I am sure Chairman Bill would claim it is OOP too (I've even heard
of there being a VisualCobol - what a dream!).

As for efficiency - Hahahaha - sure. I suppose the IEEE has a
definition for non dissipated bits?

How about a continuously loaded vertical?

I found this in the ARRL Antenna Handbook. It says to take 1 wavelength of wire and wrap a linear coil around a non conducting support which is at least 0.05 wavelengths long. So, for 40m this means wrapping a 7 foot fishing pole with 122 feet of wire.

Has anyone ever tried this? I am really liking this idea as being the most compact. If I could figure out a good removable/reattachable connection between sections of a pole, I could pre-wrap a small fishing pole with the wire, then once on-site, assemble the pole, connect the wire between the sections somehow, then be on the air, or fish if no one is on the band.

Hi Jim,

There are no hard and fast rules other than "more wire - higher up."

ANYTHING will do to satisfy this one rule.

To optimize your signal gathering capability, you might want to put
either a tuner or a tunable pre-selector in front of your receiver.
This is to protect your rig(s) from front end overload (this may not
be a problem in Saskatoon).

Enjoy your DXing.

I have J.Carr "Practical Antenna Handbook" and it is
excellent - very practical antenna presentation with
only few equations. There is available another book by
Carr: "Receiving Antennas" (if I'm not mistaken) -
I saw it in a bookstore - it contains everything that
you could need to get started.

"ARRL Antenna Book" is also very good but more difficult
to follow by a beginner. It contains more info regarding
various antennas calculations.

Hope this helps.

Hi David,

The problem comes from the possibility of erecting a vertical/sloper
that is considerably longer/higher than other options available at the
beach. This answers the objection above in that what was not a
problem at home is now a problem along the shore. It is basically the
very simple fact that wind will strip your wire of electrons building
a static potential WRT ground. Wind at a beach is probably much more
vigorous than that found in the backyard of a suburban domicile.

The solution is to drive that (bare) wire straight into ground and to
gamma feed it. This is the standard solution in most backyards for
the same reason. There are, of course, other solutions that do
basically the same thing - all of them have some DC path from sky to
ground.

In my case I already had a working station on 40m in 1971. I built a homebrew one tube xmtr and used a cheapy SWL radio with a AMBC radio next to it for a BFO. When I was in the 8th grade I was bootlegging on 40 cw as WN5MBK...g "my initials" Never got caught either. I was a good cw op even in those pre ticket days. Of course, at that time WN5MBK was still a long ways down the road callsign wise ,but most didn't realize it. "No instant call lookups in those days". When I finally got a ticket in 77, I built a second one tube xmtr. The first had been dismantled. And I also broke down an got a hammurland<sp>?? hq-110 receiver. With a real built in bfo even. Then I found a valiant xmtr. Quite a powerhouse compared to the single 6v6.
>

>
> What a neat story! I was sort of the opposite - couldn't wait to get on

I didn't waste much time getting on the air, but upgrading didn't mean much to me unless it added to my usuable abilities. At that time I didn't even have a phone xmtr, so a general didn't mean much to me. But even at that time, I was out copying many of my general class friends on cw. I used to copy for one general friend when the going got too fast for him. And that was a long time before I got a ticket. By the time I took the novice in 77, I was doing a solid 18 wpm.

Hi David,

This (the beach scenario) is a wonderful opportunity to examine the
application of these designs, because a Kite or Ballon launch affords
you the possibility of erecting very tall/long antennas - which by
definition are necessary.

Hello,

I am a novice antenna maker and am currently working on a large loop for mediumwave. I have followed plans that I've found online, but I am a little dense regarding some of the technical details. I was wondering if someone could shed some light.

-what is the best wire to use for a loop? Does the wire have to be "magnetic," what does that mean and where can I get it?

-I am robbing an old shortwave of its tuner for my variable capacitor. I've pulled the tuner itself (the rotating shaft with two sets of fins, one that is fixed, one that rotates). Is that the only part that makes up the Variable capacitor? How can I tell which lead goes to the fixed part and which goes to the variable part?

-I want to use this with a stereo component tuner (AM) and portables. With the portables I plan to use induction (just moving it near and perpendicular to the radio). What about the component? It has a single AM terminal and a ground (plus two for FM). How would one hook this up?

I would appreciate any advice. Thanks.

If you've seen a hamstick, you've seen one of these. Of course, you can
make much more efficient versions with a wider form etc. Also with this
type of antenna if you want good performance you need a stinger on top
to act as capacitance. A helical antenna with coil the whole way up and
no stinger is not a real good antenna. But if you take the same antenna
and reduce the windings, and add a stinger to the top it will work much
better. It will vary of course, but as a general rule you will need
twice the wire or more to equal a normal 1/4 wl whip. So if you need 8
ft for a 10m whip, you will likely need over 16 ft of wire to make a
helical "4 ft " version.
With the proper design, which can include the methods of winding etc,
and the use of long stingers, these antennas can do real well. The best
designs maximise the windings near the top to act as a "lumped coil"
which will improve the current distribution. Also you can wind the
matching coil right into the base of the antenna. MK

Message-ID: <95n5jmlnb1@uranium.btinternet.com>
Source record: 170810

Hello Stan,

For 17 turns your calculated inductance has a small error. This does not matter very much because you will have to adjust the tuning capacitance to resonate it to the correct frequency in any case.

The DC resistance of the wire (ohms/KM) has nothing to do with Q. It is necessary to know only that the wire is copper and that its diameter is 1.6mm.

You do not say how you measure the coil diameter. Is it between the wire centres ? Or is it the diameter of the former over which the wire is wound ? The difference due to wire diameter matters.

From the information you give, at 28.8, MHz Q is somewhere between 450 and 600 depending on the environment in which it is used. The Q of the capacitance will also make a difference.

But Q doesn't matter very much in antenna traps provided it is not too low for the TX power. Your coil should be OK for a 100 watt transmitter.

Download program SOLNOID2 from website below. Downloads in a few seconds. Not zipped up. Run immediately. User friendly.

For starters enter in the program:- Length=51mm, Dia=22.7mm, Turns=18, Ratio=0.534, F=28.8 MHz, 800 volts.

Then look for wire diameter = 1.6mm and sum of tune capacitor plus strays = 10 pF.

For design of two-band trapped dipole, including estimate of power lost in traps, download program TRAPDIP.

If you want a high power job then there's no alternative but to have BIG traps.

2638. Re: Ground plane for supplementing radials

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-05 21:50:02 UTC
From: Ken & Mary <kenmary@interpac.net>
Message-ID: <YLKf6.1019$RM.8638@newsfeed.slurp.net>
Source record: 170747

Jason,

The ultimate ground plane for any vertical antenna would be a plane
of superconducting material extending to infinity in all directions. Since
you probably only expect to communicate to other hams here on earth, perhaps
if the superconducting material extends just to the horizon would be
sufficient. Anything less is a compromise. Of course in the real world
mechanical and financial factors dictate that we make compromises. There is
lots of data on performance of ground plane antenna with various compromise
antenna's. If you study a bunch of that data you will find that the
difference in signal generated by the antenna with the ideal ground plane
and ones with practical compromises does not justify the expense.
Broadcasters have pretty much settled on 120 radial wires stretched out 1/4
wavelength long, evenly spaced around the feedpoint. You'd have a very
difficult time detecting the difference if you cut the number in half. What
is interesting is the comparison between say four 1/4 wavelength radials and
eight 1/8 wave radials. Same amount of wire used. The system with eight 1/8
wavelength radials is slightly better. This is because near the base of the
ground plane the current density is higher. So yes a conductive plate at the
center of the radial system is better than not having one. How much better?
I don't know. If you've already got the material and you're not going to use
it for anything else, I say "go for it". Also if you're going to have a
large radial system a large diameter disk to connect all the radials to is a
good way to do it. Much better than a bunch of eye lugs stacked on a bolt.
If you have the disk it's going to be easier to add radials as you scrounge
more wire.
The bottom line on radials is that more is better, and a few good ones
may be as good as you need.

Have fun, Ken N6KB

2639. Re: Trap calculation help requested

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-05 22:11:07 UTC
From: tom_bruhns@agilent.com
Message-ID: <95n8di$kv8$1@nnrp1.deja.com>
Source record: 170812

I assume you'll use a capacitor whose Q is high enough to let the coil be the dominant factor in the Q of the trap. The inductor Q may be estimated with Reg's coil program or the one from www.saratogasoftware.com, or just from the graph and formula of fig. 3 of the Fundamentals of Networks chapter of Reference Data for Engineers. That last one gives roughly 120*sqrt(28.8)*22.3/25.4, or about 560. The Saratoga Software program, for contrast, suggests the inductance is about 2.66 microhenries and Qu is about 615. "YMMV"

Cheers,
Tom

>is a tuner the same as the rf gain control? thanks, doug

Hi Doug,

Nope, not even close. RF gain control is part of the feedback path from the IF back to the RF stages where the more voltage available from the IF lowers the gain of the RF (and vice-versa). Thus a strong signal will automatically lower the Gain of your radio so that the IF stages are not overloaded and add distortion. On the flip side, very low signal levels will cause the radio's gain to increase to find weak signals. Your RF gain control adjusts how much of this goes on in a sort of mix of manual and automatic control. The term for this is properly called AGC (automatic gain control), the improper term is AVC (automatic volume control) but it does operate equivalently. The RF gain control is in the AGC circuit. The Audio gain control is in the AVC circuit (if it exists and is not incorrectly identified as AGC).

A tuner, on the other hand, limits what frequencies can enter the RF stages. Many modern radios have RF stages that listen to every frequency simultaneously, and it is the mixing stages that establish where you are tuned and the IF stages limit the band of frequencies that are accepted for listening.

The problem of this wide open "front end" (another term for the RF stages) is that any big AM station in town can find its way to your radio and dominate your radio's sensitivity by overloading the first stage (making it, and the rest of your set, deaf). This is a VERY COMMON problem to many SWLers.

If you are tuned to the Deutsche Welle on the 31M band, you don't want the local bubble-gum station pounding the first RF stage and clobbering the Germans. To prevent this, you put a tuner in front of the radio and tune it to the 31M band and thus have it REJECT the AM station that is nearby. A tunable preselector accomplishes the same thing and also adds a stage of RF amplification BEFORE the radio sees it (two good things for the price of one). The only issue with a tunable pre-selector is that you may not need the gain it offers (just the tunability). Hence the cheap solution is to find a box and put a variable cap and inductor inside and two connectors (antenna goesinta and the tuner comesouta). More elaborate designs could include bandswitching and more tuning elements (a Ham Tuner would be an example and is perfectly suitable for your needs).

The problem with adding a tuner is knowing what settings work best.
This won't be obvious (especially when there are more than two knobs),
but within a couple of days it will become an acquired skill.

Richard,

I think you are confusing syntax, which is what Cecil wants to be context-free, with semantics, which are never really free of context. Operator semantics may sometimes be redefined in an OOP language, but OOP languages along with modern computer languages in general still usually have a context-free syntax because it is indeed easier for computers to deal with.

An example of a programming language that lacks a context-free syntax is FORTRAN, where one may validly write

```
IF = 4
IF (IF) 2,3.5
```

leaving it up to the compiler to deduce what `IF' means when it appears. A more modern programming language will usually define its syntax to disallow or avoid all such cases.

As for efficiency, if you compare the code required to implement a FORTRAN parser to a parser for, say, C or C++, it is likely to become apparent that a context-free syntax is substantially more efficient, at least for the guy who has to spend his time writing the parser for the language.

Dave,

A general problem with kite supported antennas is that every time the angle of the antenna wire changes with respect to the earth the SWR changes as well. Unless one has a good automatic antenna tuner in line, you spend all your time adjusting a tuner and little time operating. That, in a nutshell, is my experience with kite antennas.

Keep also in mind that if you live in a high RF environment then it won't work at all. I live about 1-2 mi from 15MW ERP AM/FM/TV farm for Los Angeles. My MFJ-259B is worthless. I am only keeping it for benchtop measurements of inductors and capacitors vs. frequency (plus someday I may move to a location where I can actualy use it for antennas).

Message-ID: <IKHf6.59$4s4.143893@nnrp2.sbc.net>
Source record: 170726

I recently installed an Alinco HF-70T in my truck. I'm using the Hustler antennas with the different resonators for the different bands. I bought the 10 meter resonator new and the rest I pick up used. The 15 and 20 meter resonators will not longer tune. The best I can get is about 4:1 SWR. The 10 meter will tune to 2:1 or less. I suspect the resonators went bad, but I want another opinion before trashing them and buying more.

I also have another question. While playing around with this problem, I discovered that the 10 meter resonator gets about 1.75 SWR on 17 meter and 2.5 or 2.7 on 15 and 20 meters. Would an auto tuner allow be to install one resonator and not have to switch it out on 10 - 20 meters? If so, should I go with a 10 meter or 20 meter resonator or would it make a difference? This may seem like a dump question, but I'm not too experienced in the mobile area. I know I would need to switch for 40 and 80 meters.

Thanks

Larry

Hi Dennis,

I've written compilers/translators and the efficiency you speak of is one of a consideration for the parser generator - not the user (such as Cecil). For this efficiency statement of yours to be true, the best way to perform that is with the unix tools lex and yacc which uses a sophisticated lookup table rather than chained instructions. Yes, the table is a chaining mechanism, but it too is computer generated from the syntax provided by the designer. All languages, by the way, are composed of Syntax (it generally goes without saying). The most common specification is found in the Backus Naur Form (BNF). That modern languages can cope with semantic variation is already part of their syntax (and design), and is called extensibility.

My work with compilers/translators has included Natural Language Parsing that includes a full grammar of English. English is heavily vested with what you call semantics, and yet it is reducible to a BNF representation. This is not done simply (very few Engineers have good enough grades in English to understand the problems involved).

Having designed at every level from Assembler through Java (with stops along the way to include PL/M, Pascal, Fortran IV, Flecs Fortran, a bajillion flavors of Basic, C, C++, Trilogy, Lisp, Prolog, Actor, Smalltalk) I can acknowledge some languages are more accessible to the problem I am designing for (and rarely the language forced upon me by other considerations).

Both Prolog and Trilogy, as examples of Predicate Calculus, allow me to state the problem and have the solution both in the same design. As a statement of efficiency, these two languages are the tersest and simplest to express. However these same two languages come with so much baggage that they can overwhelm a system with demands for resources. Here, in the case to be made for "efficiency," they suck big-time! When it comes to the efficiency of operation, the tables turn again and these languages glow where standard, procedural language designs gets lost in combinatorial explosions that drop their efficiency to zip point nada.

Efficiency statements for computers is still akin to nailing jelly to a tree.

I need alittle help I got a Butternut antenna all ready to put up on
my Roof cause I can not do a ground mount need some help on installing
it on a Roof cause of my Town House also need help on how to run the
ground radials on the roof any help on this please......
What kind of mast do I mount this antenna too cause it does not have
any
mounting brackets?? Also once its mounted how many ground radials must
I put on the Roof
do you just lay them out flat on the Roof?? any help please.....
Mike so cal... pager 714 266-9500 email or page me and ill call you
back thanks so much..

Roy:

After some thought... I see that I was wrong, and ... I'm going to answer my own rambling prior post here below.

In fact for a conventional transformer, i.e. one where the two windings are not wound "two in hand" but wound sequentially or in layers, or whatever, it is the, unavoidable, inter-winding capacitance which causes degradation in the common mode rejection of the transformer when it is hooked up a voltage balun. So in conventional transformers one will always try to lay up the two windings so as to minimize inter-winding capacitance. In fact sometimes "faraday screens" are placed between the windings to reduce inter-winding capacitance.

Now winding "two in hand" will tend to increase the inter-winding capacitance since the two conductors are laid up against each other very closely all along their path, and so... this will result in a lower common mode rejection when this design is hooked up as a voltage balun because of the capacitive coupling between windings.

Hence, I have now come to believe that... a transmission line balun, or a balun wound "two in hand", will have a fairly high interwinding capacitance, but because of the way it is hooked into the transmission line (application), that high inter-winding capacitance will not affect the common mode rejection. While if it is hooked up as a voltage balun it will display poor common mode rejection because of the inter-winding capacitance.

And so... since there appear to be two ways to wind a balun on a core, one being the "two in hand" or "wind the transmission line on the core" appoach, and the other methods wherein the windings are separate and not wound together, or even separated by a Faraday screen, the latter will often have less inter-winding capacitance while the former will have a large inter-winding capacitance.

When you connect the former two in hand design as a current balun, the interwinding capacitance simply becomes "absorbed" into the transmission line' natural inter-conductor distributed capacitance and so does not affect common mode rejection.

While in a conventional transformer hooked in voltage balun mode, the presence of inter-winding capacitance actually causes common mode rejection degradation.

I have now convinced myself that the current balun common mode rejection ability is not limited by inter-winding capacitance as is the voltage balun common mode rejection.

In fact a measure of the non-ideality of the current balun is probably not related to inter-winding capacitance at all, it is probably the ratio of leakage to magnetizing inductance that limits the common mode rejection of the current balun. Any one who has read this far into my rambling posting here know for sure?

And so I now believe that my statement, in my last post, that winding "two in hand" simply makes a great transformer for either current or voltage balun operation is WRONG! Mea culpa.

A two in hand wound balun makes a great current balun but not a great voltage balun, and a conventionally wound transformer makes a great voltage balun but a poor current balun.

And so, due largely to these "secondary" effects, simply making the best damm transformer possible i.e. one with low stray capacitance and low leakage inductance, will not necessarily optimize the transformer for either current or voltage balun use.

Sorry for the "rambling" but I just had to explain that to myself...

Now I ask again, can anyone reading my ramblings here suggest a measure... i.e. what is the best quantitative measure, in terms of the basic transformer parameters [leakage inductance, magnetizing inductance, inter-winding capacitance, imbalance of any of the above, what?], of the common mode rejection of a current balun?

Source record: 170742

In the early months of "No-code kills" there was a radio life saving story of a Colorado miner treated via CW instructions from a qualified physician in the valley below.

I opined that the patient might have been plucked from his high altitude perch by a helicopter in this day and age. I`ve done a Rocky mountain sight-seeing helicopter tour, so it seemed a reasonable speculation to me.

There were howls that the high altitude would preclude a helicopter rescue.

I just watched "Rainier, The Mountain" on PBS. The Park Service`s primary rescue device on Rainier which tops out at 14,408 feet, the highest peak in the contiguous 48 states, is a really big helicopter. They also have trained dogs and park rangers.

What works in the state of Washington, probably works in the state of Colorado.
I just speculated. We really don`t know all the local conditions.

Best regards, Richard Harrison, KB5WZI

Relax, Dave. They're looking for someone to design the transmitter,
not for someone to actually try out the transmitter (those ads will
appear later).

Besides, you already have a transmitter inplanted in your head.
Didn't you ever wonder why you would get some song in your head,
huming along with it for days? Some lab technician was just having a
little fun listening as you tried to sing something else in an effort
to forget the first song (you don't sing very well, especially when
you're thinking of another song at the same time).

Butch Magee wrote:
> OK! I'm lost on this one. 'Splain toomee!

This is a subject of much debate. Air and vacuum coils have very low dielectric losses. Rigid coil forms have additional losses, some high and some low. The property associated with this loss is called the Dissipation Factor and the lower the better. Here is a partial list: Plexiglas .05-.06, Lexan .0009, Teflon less than .0003, PVC .020-.007, ABS .003-.008, Nylon .02, Polyethylene and Polypropylene less than .0005, Polystyrene .0001-.0006, Acetate .003-.02, Acrylic .04-.05

As you can see, PVC is not the best choice and varies widely in its characteristics. Since a large percentage of the losses in a 75m mobile antenna occur in the coil, it's best to chose a low loss coil form. I'm sorry, I don't have the Dissipation Factor for Phenolic but I think it is pretty good.

Just about the best you can do with "two in hand" is when one of the
two is the center conductor in a piece of coax. Ten turns of RG-400
on an FT-240-61 core makes a dandy HF 1:1 balun/choke. It reduces
common mode currents in either balanced or unbalanced applications.

> Spark Gap is certainly one of the original "basics".

Are you serious??? Spark is no more a MODE than DSP. See again what that fine fellow at the above URL did with spark. It sure wasn't Morse code.

I would have expected you to know that, considering that the Icom 756 sitting here on the desk before me is also tuned to a Morse code transmission, and guess what--it will also send Morse code, since I happen to be moderately proficient at using it.

Your delusions
> of grandeur about Morse code are worrisome, Dick.

What's that you call such attacks? Ad Hominem?

Aren't you good
> at anything else in the world?

Sure I am, and I said yesterday that I'm far from being one of the better MOrse code operators you'll find out there. THOSE guys are the people who did Morse daily, day after day, for a living and they got GOOD at it. I, on the other hand, had to struggle a bit, since I did it only as a ham, but I can tell you that I sure learned what it will and can do, when humans learn to use it, even moderately as I do.

Hanging all your self esteem on an
> outdated governmental requirement is psychologically dangerous.

Cecil, you keep Adding all those Hominems and soon there won't be room for you *or* your dog in your hamshack.

Seven Threes, Good Bud. And a pair of eights to the pooch.

Dick

Who said Spark Gap was a mode? I said it was one of the original "basics".
I don't know what kind of code they used with Spark Gaps. What kind was it?

It's not an attack if it's the truth and that's my honest opinion.

You really DON'T have a clue, do you? All is well with your world,
you're relaxed, comfortable, the communications world has been well
engineered, according to current doctrine, and things are perking right

along, right on schedule. Right! Nothing whatever is amiss. And then, a little crack appears in the dam.....

When you get into disaster communications, you're now on MY turf. You don't really want to get me started, but I can tell you that over a dozen years I sat on many statewide planning committees investigating just that subject, with an subject of "Migigation of an earthquake disaster on the New Madrid Fault".
One of the early conclusions was that a wide area disaster of the sort experienced in that region in 1811-1812, when the earth shook most of the time for three straight months and included six major temblor events above 8.0 on the Richter scale, as determined later by geologists, *WILL* again occur at some unknown future time. When it does, there will be nothing that is in place that can be depended upon to survive to be useful and no personnel in the area of the event--major portions of several states-- can be relied upon to report for duty since they all are just as affected as the the rest of the population, with families and their own lives and homes to attend to. All relief must come from somewhere else, at least two hundred miles away. Before that relief can move it must be mobilized. It is expected that at least 3 days will pass before the beginnings of relief arrive in any serious quantity.
The most pressing need in those circumstances when virtually all infrastructure is severly compromoised, is communications. Information, what happend, where are the victims who need help, priorities. It happens that hams are very well situated to provide a large amount of those communications, given their wide dispersal throughout the population. I leave it to your imagination to decide how it proceeds from there. Beleive me, our planning DID include ham radio operators.

One thing more. Virtually all the natural gas supply pipelines serving the northeast quadrant of the USA today pass through this same region. When that earthquake occurs, there will be vast areas of the country besides just the area affected that will suffer longterm severe difficulties.

It might be worthwhile for you to get out and take a good look around. You've been spending too much time reading the IEEE journal, which I'm sure has a solution for every problem. The real world looks considerably different. Very few governmental entities invest scarce funding in facilities which must be held, unused, in place awaiting such an event. Government budgets just don't devote that sort of capital to it, nor are they ever likely to. Frankly the taxpayers have other priorities and elected officials know it.

You pointedly ignored the "Digital Pearl Harbor" to which I referred. If you are really interested in modern communications technology, you might want to do a web search to find out just what that referrs to. The potiential is at hand for that scenario to make a New Madrid earthquake seem like peanuts, with the entirety of civilisation relying on computers.

On the other hand, you've made it more than clear that you have about the same interest in ham radio that a CBer has in his bit of spectrum. It's nothing more than just a bland hobby, devoid of any real serious communications valur or potential. No wonder you can't imagine anyone actually being serious about such an ancient communications mode as Morse code.

2682. Butternut HF6V-X Mounting on Roof Help??

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-06 05:36:06 UTC
From: bcolenso@aol.com
Message-ID: <20010206003606.21044.00000693@ng-mh1.aol.com>
Source record: 170756

Back in the mid-80's I had an HF6V that I mounted on the roof of my house. Not a bad antenna, for a vertical.

It was mounted on a 10 foot (~3 meter) tripod on the peak of the house, with a 10 foot mast. The tripod had three 10 foot 2x4's, one for each leg, on the under side of the roof, and three 5/8-24x3" bolts for each leg (two through each tripod foot, and one at the far end of the 2x4). A big fender washer on both ends of the bolt, and RTV on top water proofed the whole thing.

At first I used the Butternut Stub Tuned Radial kit, but that didn't last the first winter here in the Detroit area. Use four radials made from #12 wire, cut to 1/4 wavelength plus 5%, for each band. You can use your 40 meter radials for 15 (third harmonic). The angle of your radials will affect your SWR, so you may have to play around with that. Start at 45 degrees and go from there.

This setup gave me many years of satisfaction. I've "talked" all over the world with it, and even the rare occasion then I pulled the mic out of the box in the drawer, I could normally break a pile up with only 100 watts.

I'd be very surprised. They don't support any of their older rigs, I believe the earliest is the TS850.

You can send an email to Terry at tandt@townsqr.com. I swapped him 430 parts rig some time back and he may make a faceplate available if he still has it.

I bought a simple SW antenna kit from Dick Smiths over here in Australia, and I can assure you that Radio Shack or other good electronic stores will have a similar kit. Anyhoo, the kit I bought has made a world of difference on my Sangean 808. I have been able to pick up a hell of a lot more now since I installed this antenna. Last week, I picked up BBC World Service from Skelton England in Sydney (at least thats what Passport 2001 reckons anyway)

The antenna is very basic, it comes with 25 metres of insulated copper wire, 10 metres of insulated rope and 2 egg insulators. Cost me A$27, and it performs really well, for a low price.

>...

No, Dick's using a different performance criterion than you are.

Exactly what the criterion is, I can't say. The challenge to the theorist
in a case like this is to figure out what the user's criterion really is.

An antenna for somewhat shorter wavelengths, Smithsonian's "Multiple
Mirror Telescope" of the 1970's was an engineering failure: the
laser/actuator system that was supposed to hold the mirrors in alignment
never worked properly. Or was it? In fact, the telescope was an incredible
success! Its lightweight structure provoked much less air turbulence in
its immediate vicinity than a conventional structure. The result was
images that were better than expected, despite the failure of the active
alignment system. Rather than deny this, telescope designers learned that
their performance criteria needed revision. The current generation of very
large telescopes could not have been built without this insight.

2691. Re: Why does a BALUN shorten antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-07 10:08:00 UTC
From: "Peter O. Brackett" <ab4bc@ix.netcom.com>
Message-ID: <95r6ns$9vh$1@slb3.atl.mindspring.net>
Source record: 170764

Reg, Cecil:

Hey thanks for the feedback. I agree with Cecil that winding the coax transmission on the core makes a great quick and dirty current balun or common mode choke, and Reg's speaker wire construction is my personal favorite, since I hate coax... but... I still wonder how does one "optimize" the design of a current balun? i.e. how many turns of the two in hand, how close should they be spaced, how big should the core be, what are the secondary effects that cause loss of common mode rejection capabilities, etc, etc...

I am still curious and ask... if one were to take an existing "current balun device" and characterize it's "primary" parameters, instead of it's "secondary" parameters. e.g, leakage inductance, magnetizing inductance, capacitance, rather than total common mode impedance, how can one calculate it's common mode rejection.

How can one tell if one current balun design is better than another. Which one to buy? Etc....

I know Reg will say, once it's good enough, there's no need for the average ham to make it better, it will only affect signals strength by 0.001 S Units, and so... who cares, but "I am curious".

As my sons used to say when they were young, why daddy?

If one measures the primary capacitance parameters on a conventional transformer, i..e. interwinding capacitances and their imbalances, then one can more or less calculate the "mid-band" common mode rejection from those capacitance values.

Understanding the physical makeup of those inter-winding capacitances guides one in the physical construction of conventional transformers having high common mode rejection, up to and including the design of Faraday screens between windings which can really help to generate very high common mode rejection. But I just don't get it yet, and I wonder what the "rules" are for designing a good current balun?

What are physical parameters and approachs applicable for designing high common mode rejection for a current balun? Will simply winding on more turns of the transmission line, "the two in hand wires", create higher common mode rejection, or will some maximum be reached and then fall off, etc... i.e. when have you put too many turns on the core, and...

Perhaps winding the transmission lines on the core in a fractal pattern will help? Fractal balun's ought to be better than straight baluns, no?

In other words, I wonder, what are the guidelines for and how does one "optimize" the physical design of a current balun, not just make one that's "good enough for government work" or perhaps "good enough for ham use".

Thoughts, comments?

-Peter K1PO

> why this is the convention.

Perhaps it is because of the calculations of Longitude and position where:
The distance per degree of longitude at the Equator is about 111.32 km
(69.18 miles) and at the poles, 0.
Longitude gives time and Time gives Longitude when combined with a star
observation. But you will require Latitude to apply the appropriate
distance.
i.e (Degrees Difference Longitude) * Cos (Latitude) * 69.18 miles

> Easting/Northing are given in this order.

Yes, what about Postcode? :)
Sorry that's a local joke.
Though I do have a CD-ROM that can translate from Postcode to Easting and
Northing, but it is by means of a look up table.

> I assume this is because Easting and Northing are
> xy-coordinates on a map projected onto a plane.

Yes indeed but ther is a mathematical relationship that is used by programs
and GPSs to convert between the co-ordinate systems.

The 'x' is equivalent to Easting and Longitude

And 'y' to Northing

Have you seen the marvellous film about Harrison;
or read Dava Sobel's book "Longitude"?

I'm sorry but I must disagree.
Receiving Antennas are identical to Transmitting antennas except it on the one hand their power handling and on the other hand noise pick up, and the fact that generally speaking a Transmitter will usually only be operated over a very small segment of the band and the Antenna may be made resonant and it doesn't matter a damd about noise pick up.
A receiving antenna on HF will be required to look at a broad spectrum generally most people woykl like it to go from 1 MHz to 30 Mhz with good performance all the way through, or at least good performance on all of either the Hma Bands or conversely the Broadcast bands. Meeting the criteria of performing reasonably over such a wide spectrum is a daunting prospect. But more importantly is the consideration of noise pick up. Too much of this and you might as well just use a small whip that is part of the receiver. There will be lots less signal but also less noise permitting you to hear the few signals that you can pick up.

Most receivers have more than sufficient sensitivity for the HF bands, (Many far too much), but the signals that you will be able to hear all depend upon the quality and location of your Antenna/ Aerial.
A good Earth is also an advantage.

Ahh, the crossed-field antenna. Surely the "Phoenix" of antenna designs. I can't comment on commercially-available amateur versions, but if you want to build one, there were construction articles available at www.antennex.com. You might also want to read the article by Dr. John Belrose at this site if it's still available. I would also encourage you to read the previous postings on this ng and perhaps others (do a search at www.deja.com). Personally, I would rather spend my time constructing some of the antennas in the ARRL publications (e.g., Handbook for Radio Amateurs, Antenna Book, Antenna Compendium, QST). Unlike the proponents of the CFA, the ARRL authors appear to know what they're talking about. Best of luck. 73s,

Bill Nelson wrote:
"All that is needed for most emergency communications is CW or voice - not video."

A video baseband can carry hundreds of voice channels. Let`s see, 5000 KHz divided by 4KHz is 1250 channels. That is exactly the way it is done with old fashioned frequency division multiplex. Digitization uses time slots in place of frequency slots, but the relation between frequency and bandwidth remains.

The single-channel network equipment I mentioned is only providing one voice channel. This means narrowband equipment equipment is being used.

The slice of noise accepted is proportional to the bandwidth accepted. So, a smaller dish can be used with a single channel because not so much signal is needed to overpower the noise accepted.

On the other hand, the TV remote vans use large dishes because they have 5 MHz of bandwidth to convey, and accept a 5MHz slice of noise. They need proportionally more signal strength for the same signal to noise ratio. Larger dishes produce larger power gains to get the larger signal strength needed.

Best regards, Richard Harrison, KB5WZI

Daunting prospect? With that, I disagree. There's just not a lot of
difference, receiving, with a miscellaneous-length long wire or dipole
versus a dipole tuned perfectly to the frequency. Maybe the resonant
antenna will have an advantage of 1 or 2 S-units, maybe not.

The original poster seemed confused by all of the conflicting
information he'd gathered on antennas, and I was trying to steer him
to something simple. A long wire, indoors or out. A misc.-length
dipole. A Radio Shack swl'ers wire dipole. Something like that.

Yes, there are noise considerations, and problems with front end
overload on the less expensive shortwave receivers, but you've got to
start some place, and an odd length of wire, indoors or out, or a
Radio Shack wire dipole for swl'ers, options like that would be about
as good a way to go, and if there are problems, then you at least have
a starting point.

On rereading my explanation of why it is often possible to use smaller dishes for voice than video, I see a clarification may help.

The bandwidth of the receiver determines how much noise it accepts. A voice channel receiver needs only about 4 KHz bandwidth. The usual video receiver needs about 5 MHz bandwidth.

More received signal produces a better signal to noise ratio, for a certain amount of noise.

The wider band receiver accepts more noise, so it needs more signal.

Best regards, Richard Harrison, KB5WZI

Hmmmmmm....I put an ATV signal on the air with a yagi that
measured just over 1 meter long. No big dish needed there, and the
bandwidth was comparable.

> They need proportionally more signal strength for the same signal to
> noise ratio. Larger dishes produce larger power gains to get the

THERE YA GO!......The size of the antenna (other than simple
wavelength considerations) has little if anything to do with the
bandwidth of the signal. The desired gain has exponentially MORE to do
with it's size, however.

That would be like shooting an elephant with a pea shooter.
Writing about Mt. St. Helens in a March 1981 Scientific American
article, Robert and Barbara Decker wrote, "The volcano's sustained
power output might therefore be compared to the serial detonation
of some 27,000 Hiroshima-size bombs: nearly one a second for
nine hours."

Well, the antenna gain required depends on path loss and transmitted power in addition to the minimum acceptable received carrier power.

You see the tiny dishes used with Direct TV. That is possible because the power transmitted by the TV satellite is relatively high.

The voice-frequency network doesn`t use nearly as much power. It is a cheap service. But, the voice-frequency network gets away with small earth dishes because it uses narrowband receivers.

K4YZ`s yagi probably wasn`t trying to reach a geosynchronous (geostationary) satellite 22,300 miles above the earth.

To compare apples with apples, the transmitting frequency must be considered. A small dish at a lot of gigahertz can have more gain than a 1-meter-long yagi at 1/2-gigahertz.

2714. Details on why ground plane is needed

Newsgroup: rec.radio.amateur.antenna

I know that a ground plane is needed for a 1/4 wavelength monopole antenna. I'm trying to gain a good understanding of why this ground plane is needed.

1. Exactly why won't the antenna perform if you don't have a ground plane? I know that the ground plane is needed to provide a conductive path back to the antenna. But why is this conductive path necessary? And what happens to the RF if this ground plane is not present? My general understanding is that the RF is reflected, and the reflected RF is out-of-phase with the original RF, thus cancelling out the radiation. Can someone provide more details on why the reflected RF is out of phase? (I'm not afraid of a few equations.)
2. If the antenna is shortened through loading schemes (capacity hats, loading coils, etc.), is the size of the ground plane required also smaller? Does a shorter antenna have a different near-field and far-field radiation pattern than a full size antenna?
3. How exactly does ground conductivity matter? It seems to me that there would be a VERY high resistance between the antenna and a point in the far field of the antenna.

Tom Donaly, KA6RUH quoted a "Scientific American" article:
"The volcano`s sustained power output might therefore be compared to the serial detonation of some 27,000 Hiroshima-size bombs: nearly one a second for nine hours."

Wow! What leverage, but even if Fuji were centered in downtown Tokyo, the Japs probably wouldn`t have believed in the atom bomb without its unadorned exhibition.

My shipmates and I had no idea what an atom bomb was, but it seemed as if it might mean we would be going home soon. We got to see the devastation at Nagasaki before coming home, it turned out. Awesome.

Not just economics. Also a mindset that bad things don't happen very
often. The same sort of thinking that led to inadequate lifeboat space
on the Titanic and the Challenger disaster. "We don't worry about that -
the chances of it happening are too remote". Uh-huh.

Someone is selling junk somewhere. This is not the first case I've heard of bad 213 coax. I also heard a guy on the radio talking about it, BEFORE Floyds post, saying they bought 1000 ft of 213 that had twice the normal loss. I don't know Jim, or Bob, or Elwood, or any of the other wire sales dudes/dudetts around the world, but someone IS selling junk 213. If I remember right, the company that sold the junk 213 to the guy I heard on the radio, WAS NOT radioworks. But I'd almost bet they are selling the same shoddy overseas coax. To me , these companies which apparantly are buying this bulk 213 are victims of shoddy product also. But I wonder? Don't they test random samples of this stuff before they sell it? MK

There's a lot more to it than that,of course. The higher the frequency the smaller the dish which will deliver the same gain. The small DTV dishes operating on or above KU band will deliver the same relative gain that a much larger dish operating on the C band.
Then there's the factor of much improved microwave amplifying devices. In the C band satellite TV days a 100 degre Kelvin Low noise amplifier needed a 10 foot diameter dish to deliver a noise free picture on the weaker satellite transponders. Much improved noise figures in microwave amplifiers allow dish sizes down to 4 feet to be useful. And on KU and up, those amplifiers with much improved noise figures coupled with digital compression technolgy allow virtually perfect video with an 18 inch dish.
Actually, the use of higher powered transponders is not necessarily needed at all. Frequency and receiver electronics are more likely to be the reason. Power is at a premium on satellites, of course, so higher transmit powers would be the last option to be put in use.

> The voice-frequency network doesn`t use nearly as much power. It is a

But these earth stations are not all that common, and are almost all highly specialized as to use. The eariliest communications needs in a major disaster are communications NOW, with no time to arrange for acquisition, transportation setup and operator availability. Hams have all that builtin.

Bandwidth and gain are two diff'rnt critters, Richard.

>K4YZ`s yagi probably wasn`t trying to reach a geosynchronous
>(geostationary) satellite 22,300 miles above the earth.

My ground plane for 2 meters made it to Mir. Twice. A friend of
mine routinely works EME with a 2-yagi array on 432 and 150 watts.
That's 20 times farther (round trip) That's about .0003 watts per mile
if we discount all the attenuation up and down, etc.

>To compare apples with apples, the transmitting frequency must be
>considered. A small dish at a lot of gigahertz can have more gain

We don't have any allocations at 500MHz. (At least I don't).

Current needs a closed path. Installing radials decreases the
dissipative resistance in the closed current path thus reducing
losses. Wire is less lossy than earth.

Steven, K4YZ wrote:
"Bandwidth and gain are two diff`rnt critters."

Yes they are. Often they are antagonistic. That is, gain must be sacrificed for bandwidth or vice versa. That is not the issue here. The antenna bandwidth is not the problem. Noise is a function of receiver bandwidth.

Noise distribution is almost constant in a segment of bandwidth. So, a wide receiver bandpass lets more noise through than a narrow receiver bandpass does.

A video receiver requires a wide bandpass. An audio receiver does not.

The video receiver will filter out less noise than the audio receiver. So, the video receiver requires more signal to overpower the noise.

http://www.primenet.com/~ctrask

There is a lot of activity going on at present. The Italian RAI replaced
a vertical with one, and it worked well enough that the vertical was
removed, or so the engineer says in the interview in Radio World recently.
There are two under construction in Brazil, a couple here in the US, and
more in Europe. The Isle of Man installation is about to undergo (or
maybe already undergoing) testing after being delayed.

doug schrieb:

> is a tuner the same as the rf gain control? thanks, doug

No.
RF-gain control is used to only decrease *all* the power coming from the antenna. This is used to prevent frontend overload (mostly recomended on the "cheaper" radios below US$1000 ;-)) and to lower the overall noisefloor to get a slightly better signal to noise ratio.

A tuner is used to match the impedance of the antenna to the input impedance of the RX (most commonly 50 Ohms on PL- or RCA- connectors). This is for giving best performance on a specific frequency to prevent loss on weak signals. Using an antenna not resonant to your specific frequency you may have a better signal reading on a S-meter and a little decrease on other (out of band) signals. So it gives you a better sensitivity and selectivity in some cases.

Using a tuner on a TX is just another theme :-)

On the other hand, there are a number of commercial organisations and broadcasing companies who are taking an interest in CFA's. Some CFA's have already been erected and more are in the planning stage.

But this situation can be explained by assuming the engineers employed by commercial organisations and broadcasting companies are just as scatterbrained and as gullible Ph.D's as the 'inventors' of this marvellous extra-Maxwell antenna.

It seems the storm in a teacup is still raging.

There is no optimum length of line or cable to be wound on a 1-to-1 current balun. Just get a lot of turns on the core. It matters very little what a lot of turns means. In some cases zero turns are satisfactory. But at 1.9MHz, on a lump of ferrite, 9 or 10 turns are good enough. That's if you really need a balun of course.

Just limit the length of the winding to no more than 1/8th of a wavelength at the highest operating frequency.

On the other hand, if everybody took THAT common sense viewpoint, there would be nothing for the annual handbook and monthly magazine authors to review or write about. Technical editors would have difficuly in justifying their salaries. Amateur radio newsgroups would lapse into oblivion. Great unemployment in would ensue.

I have found the answer by searching through old patents. For UHF you
can use a 3.5 X 14 bowtie, something with a ~ 30 deg inc. angle on each
7 inch side.

I'll report results after trying this.

The I.o.M. installation was refused planning permission recently, Chris.
I believe they are now looking for another site, still in the I.o.M.

A test mast is being constructed near Cosford in the UK midlands.
Engineers from BBC, Merlin, Crown will be invited to inspect and monitor
tests. Frequency probably 972 kc/s.

Cecil said succinctly what I`ll repeat, more or less, in other words.

Though you may have no jumper wire between a vertical antenna (radiator) and its ground plane, you can have a current flowing in the space between them.

In a wire you can get r-f "conduction" current. In space you can get r-f "displacement" current. This is just like the a-c current you can get between the plates of a capacitor.

If your antenna`s displacement is only between the radiator and ground plane wires, the loss will likely be low because no lossy ground intervenes.

If your antenna`s displacement current includes some lossy ground in its circuit, antenna efficiency will be lowered.

>Best regards, Richard Harrison, KB5WZI

Hi Richard,

It must be remembered that at a higher frequency (if we are to compare the power capturing ability on par values) that antenna MUST have more gain to operate equivalently to the lower frequency, lower gain antenna.

This has to do with the power illumination of the service area by satellites. These small antennas have to capture a certain power level that is measured in W/cM (or more likely uW/cM). This is the principle boundary condition that must be met for any service.

The large 12 foot to 20 foot models were capturing a certain power level to satisfy the signal to noise ratio for the TV (and all things considered) - lets call it 1 uW (an arbitrary value for the purpose of discussion).

Lets say that we are operating with the smaller 12 foot model which presents a total area (aperture) of 100,000 sq cM. We thus have 1 uW total absorbed from 100,000 sq cM which is an equivalent statement that the satellite is illuminating the surface of the earth with 1 uW/100,000 sq cM.

Two different ways of looking at this is
10 pW/sq cM
or
10W/1000 sq kM
which roughly corresponds to the older, lower fequency generation of satellite radiated power level for its fixed service area.

NOW, if we raise the frequency, the same wavelength proportional area is found in the smaller antenna, but the power level will drop in the inverse physical proportion, hence the higher frequency antenna must either have more gain, or the satellite must emit more power.

I can hazard a guess that the new generation of higher frequency satellites radiate more power by virtue of this frequency AND to

satisfy a market that demands a solution smaller that 12 feet across.

Engineering design is driven more by market pressures than pure engineering requirements.

I'm no antenna guru however I can share my experience with you. When I got my ham ticket, I went out and bought a Gap Titan vertical, mainly because I don't have a lot of room here for dipoles. I suspect you may be in the same situation. The Gap worked fine, but it was a sizeable investment for me and I was always worried about it in wind/ice storms. Also, if something goes wrong with it who will fix it?? It will be up to you. I now use a dipole in my attic, I had to put a lot of bends in it to get it all in there but it works.
My advice is: put up a wire antenna, if you get a chance try someone elses vertical to see if you like it, then decide.

Brian

Not a guru, but have had some antennas ...

Both are rather expensive, and don't necessarily work better than a simple wire dipole. If you can get 100 feet of wire between 2 supports (trees, chimney, whatever) and can get it up off the ground (the higher the better) you can make an antenna that'll work nearly as well for the price of copper wire and coax.

I have owned the Gap Titan (didn't think much of it especially on the low bands), Cushcraft R7 (overpriced and prone to flakiness), Cushcraft R5 (best of the three, but still had blown traps with only 100 W output), and have a brand new R7000 in the basement (where it's been for three years).

Verticals antennas are supposedly better for DX, due to a lower take off angle, but even so, a resonant dipole at 1/2 wave or more in height will do just as well.

I now run a 30 meter resonant dipole, a 20 meter resonant dipole, and a 136 foot 80 meter resonant dipole that I can match on all bands with a transmatch. None of 'em higher than 25 feet. I plan to string up a 40 meter resonant dipole as soon as the snow melts off the roof. At that height, only the 20m and 30m are optimal.

While I can't say I've worked much 80 meter DX from my QTH in Connecticut (but I have worked some), I've done well on 40, 30, and 20. My logs for January show France, England, Northern Ireland, Spain, Azores, Romania, Galapagos Island, Cayman Islands, Ukraine, Finland, Czech Rep., Mexico, Greece, Germany, Belarus, Macedonia, Guadeloup, Bulgaria, Croatia, and more. Often on less than 25 watts output, some on as little as 4 watts. Easy DX, to be sure, nothing rare, but all a lot of fun! Besides, when you first start out, any rare DX you get is more a matter of luck than equipment and operating ability.

On the VHF/UHF side, a simple home built vertical ground plane does the job. Or spend $75 on a commercial vertical.

With the money you save, buy a good (not MFJ!) transmatch (most call 'em antenna tuners) with a good balun. Once you see what I wire can do, you'll want to use twin lead and ladder line to make your wires really sing.

Don't waste your money on complicated wide-band or multiband dipoles that utilize traps. They're expensive, prone to mechanical and electrical problems, and are usually inefficient on any freq except the very highest for which they're designed.

With one exception ... the W9INN antennas have extremely good user reviews on www.eham.net. And they ain't cheap.

Good luck, enjoy the HF radio, and good DX!

From: Doug <n0hqn@yahoo.com>
Message-ID: <95st30$jm4$1@nnrp1.deja.com>
Source record: 170713

Hi, all....

Am THIS close to purchasing the HFV9 but have some mounting concerns. I've read the Bencher PDF files--good stuff, BTW. I'd like to ground mount the vertical to take best advantage of a good radial system, but don't necessarily want to plant it squarely in the middle of the back yard. Has anyone mounted thier vertical closer to the house without severe detuning problems (oh, say 6 feet away from metal siding)?

Otherwise I was considering the old mast next to the house and anchored to the eave idea, with the antenna base up about 10 feet. That's fine-problem solved, right? But now how about the radial system? Don't really care to have radials on the roof.

Any input would be GREATLY appreciated!

Doug--- n0hqn

While you say you disagree with me, your answer seems to support my belief the value of a preselector depends in part on the receiver you're using.

I was told with my radio, and my location, a preselector would provide no benefit, and reduce my ability to receive weak signals. So I didn't buy one.

Richard Harrison wrote:
>
> Dick Carroll wrote:
> "You speak on banal generalities and claim them to be fully
> comprehensive facts."
>
> Morse code is obsolescent in amateur radio and already obsolete
> elsewhere.
> That is the truth without obfuscation. Can`t say the same for Dick
> Carroll`s obtuse statements.

Let's enumerate a few other well known items that are obsolescent and obsolete but are still in widespread daily use-

Piston engined aircraft
Amplitude modulated radio
Single Sideband radio
packet radio
Frequency modulated radio
gasoline powered internal combustion engines
coal fired electric generating power plants
Analog TV
Boeing B52H bomber
F16 fighter aircraft

This list could go on and on, but I think the point is well enough made.
Obsolesense or becoming obsolete does nothing to detract from the utility nor the functionability of a system or device, it just means that later technical developments have made that system or device something less than the optimal choice in most settings where cost and availability are not major factors. So it is with radiotelegraphy, the simplest, most easily implemented radio communications mode yet devised. Any device that will generate an RF carrier can be on-off keyed encoding Morse code to send a radio message.

There are indeed any number of more advanced communciations systems available, some of them mentioned above, who are themselves obsolescent or obsolete, but which are not generally considered to be, and which are still in widespread common use.
So long as radio amateurs use Morse on radiotelegraphy at a rate anywhere approaching a small percentage of that in current use, it is of no consequence whatever that it falls in the same category.

So again, your assertions are so much vaporous personal opinion. As Cecil says, opinions are hung on the back of everyone, and you've got

yours, too. But that is just what it is - your opinion.

2742. DK3 MOBILE HF ANTENNA QUESTION

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-08 02:06:35 UTC
From: Ed Lyons <elyons@sympatico.ca>
Message-ID: <3A81FE3C.D2277C5B@sympatico.ca>
Source record: 170715

I am in the interest on building the DK3 Hf mobile antenna. I have all the plans how to make it. Anyways, the question I have is the loading coil form is made of 1 1/2" skep 40 PVC pipe white. Does it have to be the color white??
The reason I ask is that my local supplier have the plumbing black sked 40 an I found the plastic conduit grey sked 40 for electrical.The white would have to be ordered.

Now I was told that for the black PVC it has pigments of metal to form the black color and could cause a change in the inductance of the coil. Is this true???

Thanks in advance.

Steve, K4YZ wrote:
"We don`t have any allocations at 500 MHz---."

That`s called rounding. For illustration, I thought 500 MHz was close enough to an ATV frequency. You can scale the results to any frequency you like. We started with microwave frequencies used with satellites.

The most popular high-gain microwave antenna is the parabolic reflector type which is illuminated at its focus.

Parabolic antenna gain depends on its size in wavelengths. The gain is proportional to the square of the dish diameter divided by the wavelength. There are constants and efficiency factors needed for the actual gain number.

A typical 6-ft dish antenna has a gain of 38 db at 6 GHz.

A 36-ft dish has a gain of 38 db at 1 GHz.
The wavbelength was 6x the 6 GHz wavelength and the dish diameter was 6x the the 6 GHz diameter, so the quotient of the dish diameter divided by the wavelength is the same in either case, giving the same gain at 1 GHz or 6 GHz.

A 3-ft dish has a gain of 38 db at 12 GHz.

A 6-ft dish has a gain of 44 db at 12 GHz,
4x the gain of a 3-ft dish or 6 db moere than the gain of a 3-ft dish.

As for yagi antennas, the ARRL Antenna Book has gain versus boom-length charts. A 1-meter boom at 500 MHz would be 1.6 wavelengths. The charts indicate this might producre a 13 db gain.

This exercise is just to give an idea of the antenna gains that are achieved with these antennas.

Best regards, Richard Harrison, KB5WZI

OK, I have one of these little things from a long time ago when I could only really listen to CB:
http://cgi.ebay.com/aw-cgi/eBayISAPI.dll?ViewItem&item=1211275066

Would it be at all possible to rip the existing antenna out and build one for 2 meters into it? The reason I want to do this is that I have this same antenna mounted on the side of my window of my house, painted to match the outside of it, and it is perfectly hidden from everyone (this is a plus since I can't have any outdoor antennas). Would this be an easy project or would this body be too short? I am currently running a discone in my attic but a crappy satellite and cable television install has left me unable to use any of my radios until I can re-run and unscrew-up what the cable and satellite guys did due to TVI. This antenna looks perfect and already has a nice out-of-the-way mounting space. Can I do it? Any suggestions are welcome. Thanks and 73~~!!!

If you are limited to a vertical, I'd suggest the Butternut HF6V. I was limited to either a vertical or an attic dipole and after much research settled on the Butternut. I have never been sorry of the purchase. I worked many DX countries with great reports. If you are worried about durability, don't be. It survives severe winds here in Arkansas and even the great ice storm during December. You can check out review on the Butternut and other antennas at www.eham.com . Granted, a long dipole might be cheaper and as good, and a yagi would be great. However, there is times when the dipole or yagi just can't be installed.

Source record: 170622

Hey folks after cogitating for a while, on what Cecil said, "It's simply an RF choke for the common mode", I think I have figgered it out.

The effect that would most tend to reduce the common mode rejection of a "two in hand" wound current balun is...

ta da... "intra-winding" stray capacitance! Similar to the "self-capacitance" of a common inductor or RF choke.

I say "intra-winding" capacitance rather than "inter-winding" capacitance because it would be the "turn to turn" capacitance of the transmission line pair of conductors, rather than the capacitance from conductor to conductor of the transmission line, that would tend to reduce the effectiveness of the choke.

And so.. just as with the design of RF chokes, i.e. where often their windings are grouped into "pies", spread out on a former to reduce the inter turn stray capacitance, by creating a series connection of physically separated smaller chokes, then the windings on a "two in hand" choke balun should be spaced out to reduce that same intra-winding capacitance.

And probably just trying to achieve higher and higher inductive reactance by throwing on more and more turns becomes counterproductive for increasing common mode rejection.

Now I have come to convince myself that probably the best way of increasing the common mode rejection of choke baluns [current or transmission line baluns] is to series connect several smaller ones, with fewer turns, spread out along the transmission line being "choked" rather than trying to achieve all of the common mode rejection in one big lump with one compact component.

Of course Reg will chime in and say that "one is good enough for ham radio work" and he is right, but I wanted to try to understand the first principals better.

Now... it seems that common mode rejection for both conventional transformers and transmission line transformers is really ultimately limited by the secondary effects of stray capacitances and is not really [ultimately] limited or controlled by magnetizing inductance or the ratio of magnetizing to leakage inductance.

What a revelation! Stray capacitance is the ultimate limitation for both kinds of baluns.

And that... after a sufficient magnetizing inductance is achieved [i.e.a critical number of turns] for either a current or voltage balun design, that adding to the magnetizing inductance by increasing the number of turns will

only increase the inter or intra winding capacitance and so ultimately reducing the common mode rejection of the balun.

Now thinking about a conventional transformer balun, it potentially has the advantage of the use of a Faraday screen between the windings as a possible way to reduce the effect of interwinding capacitance, while a Faraday screen would be all but impossible on the current or two in hand transformer. Problem is where to connect "the ground" on the Faraday screen. Especially if the voltage blaun is way up in the air at the feedpoint of an antenna!

However, another way of increasing the common mode rejection of a conventional transformer/voltage balun is the "cascading" of conventional transformers. Each transformer that is cascaded adds more inter-winding capacitance in series, with the common mode path and adding caps in series reduces the total capacitance.

Cascade connections of voltage baluns will put the inter-winding capacitances of both voltage transformers in series thus increasing the common mode rejection.

And so... putting current baluns [i.e. RF choke "pies"] in series will allow a decrease in intra-winding capacitance and an increase in common mode rejection, while putting conventional voltage baluns in cascade will achieve a similar objective by reducing the overall inter-winding capacitance.

Whew... after all of that "splaining" it comes down to the fact that both types of baluns voltage and transmission line which are both, based upon primary parameters derived from "magnetics" are ultimately limited in their common mode rejection performance only by secondary parameters of stray "capacitance".

There seems to be "the hand of God" in that physical result. The two balun techniques are not really that different! Both are limited by capacitance.

And for the transmission line common mode reductions applications the current, or two in hand, balun is probably the surperior technique because to a first order the larger interwinding capacitance gets "absorbed" into the transmission line's distributed capacitance, and it is only the "smaller" intra-winding capacitance that affects its common mode rejection. While for the voltage balun the larger inter-winding capacitance is the dominant effect.

One type of balun is limited by inter-winding capacitance and the other is limited by intra-winding capacitance. And inter-winding capacitance will always be larger than intra-winding capacitance simply because of the physical "lay up" of the winding technique. And so the current balun will likely be a superior or more effective design than the voltage balun for this antenna feedline application, i.e. more common mode rejection in a smaller less complex package.

More dB's of common mode rejection per dollar for a current balun than for a voltage balun.

And... if one doesn't fix the problem add serveral more in series!

Which we all knew anyway...

As Reg would say, "a tempest in a teapot".

But I'm happy because, even though many before me have figured this out, "now I know"... stray capacitance limits the ultimate common mode performance, but...

Consistent with the title of this thread, it is probably the leakage inductance of the balun which causes the antenna element to be shorter than expected... sorry for the topic drift folks...

Happy balun winding...

-Peter K1PO

It's probably true, and I note that unless you have the latest version from
W6AAQ, you may want to spend $5 for the plans from him. You can of course use
other plastics, but be sure they don't have RF problems.

No they don't.

I used to work at a coaxial cable importers here in the UK.

the 'Italian' manufacturer initially sent us over a selection of
different grades as samples. From memory they were poor to very poor to
some stuff I wouldn't give my grandmother.

The final question they asked via fax was "Tell us what you would like
printed on the outside of the cable!"

I'll leave that last one up to your imagination.

Sorry I don't have time just now for a lengthy response. But don't forget the useful maxim "If you can't fix it, feature it." If the choke is primarily inductive (as opposed to resistive, which many are), capacitance can be used to resonate the choke to form a parallel resonant circuit. The result is a choke with higher -- perhaps much higher -- impedance than you'd have without the capacitance, but only over a narrower band of frequencies. This principle is used for the "air core" baluns made from coiled transmission line you'll find described in the _ARRL Handbook_.

The objective is to get an adequately high common mode impedance to reduce the common mode current to a sufficiently low value over whatever frequency range is required. How you get there is of little consequence to the end result. The salient figure of merit is the common mode impedance.

The main consideration is height.
Though not accurate as a generality for a beginner perhaps you are justified in saying this, however I've wasted enough hours on bad AEs over the years to not wish that upon a new comer. It is worth spending a bit of time on string up a good AE and not accepting the first thing that happens.

But I will agree that any antenna is better than No aerial. That having a go is infinitely preferable to sitting on your hands.

Yes Bob that's laudable and I agree with you, however I do not want to see the myth that any old bit of wet string will do for receiving whereas you have to take extra care for a transmitting Aerial. The fact is that if you make a mistake on either AE you will pay a penalty, it's just that if you have a bit of power around your attention will be drawn to the mistake in a salutory way.
With a poor AE intended for receiving you will just waste many hours chasing that elusive DX that you can't hear because the AE just ain't no B good. :)

I've tuned up a steel veranda fence to transmit before now and got out OK,
but it wasn't that great for receiving.

A bit of time spent making a simple preselection tuner of even just one
section is probably worth while. Never the less I agrre with you that
getting started regardless is the MOST important thing.

Isn't it funny, when I smoked I wanted others to share my misery by handing
my fags around, when I drank I handed the booze around, does that mean that
because we are hooked on Ham radio that it will be good for everyone else?

Reducing RF gain does not lower noise floor,
it raises it.

The apparent improvement in S/N is because you can
only see the stronger signals,
which by virtue of their greater strength
already have a better S/N ratio

> A tuner is used to match the impedance of the antenna to the input
impedance of

An ATU will match the impedence, however what is required for reception is a
tuneable passband filter. Preferably at least three sections for Ham Band
use.

cases.

The bigger reading on the S-Meter will most probably be due to all the extra
noise that is coming in the front end, not due to any increase in signal
level.

Remember S-Meters indicate SIGNAL AND NOISE not just signal.

> Using a tuner on a TX is just another theme :-)

Oh! Who composed it? :)

Having said all of that the answer to the original enquirer is still NO

Reg wrote:
"In some cases zero turns are satisfactory."

Why wouldn`t the W2DU ferrite bead balun be preferred? It presents a high impedance to prevent antenna current access to the coax exterior over the entire h-f range.

If you don`t want to put a balun at the dipole feedpoint, why not make a parallel resonant circuit of the coax exterior by whatever reactance must be added at ground level?

Reg already suggested using a 1/4-wave (or odd multiples thereof) for a feedline, and making sure there was a good ground at the radio. That will work, but it is centered on a single frequency. If you add a tuning mechanism for the exterior of the coax, you should be able to adjust the line to produce a high impedance at the antenna feedpoint and thus reject feeding current from the antenna into the coax`s exterior. For convenience, you would do the tuning at ground level.

The tuned coax exterior should not affect the differential mode operation of the feedline.

Best regards, Richard Harrison, KB5WZI

Reg Edwards wrote:
> Hello Cecil, what is the desired impedance to the common mode currents ?
> In ohms, R+jX or Z Theta, please.

My balun/choke is close to my transmitter. Without the choke, the impedance seen looking back down the outside of the coax braid is very, very low. The impedance referenced to ground seen looking into the ladder-line is somewhere below about 60 ohms. So the common mode impedance at the choke needs to be at least 200 ohms or more. Inductive reactance is preferable but resistive will do. There's a formula for the number of turns given the desired inductance and the AL (mh/1000T) constant for the ferrite toroid. Note that what I am trying to prevent is conducted common mode currents. Inducted common mode currents are somewhat unpredictable and are best dealt with by a good mechanical layout of the antenna system.

A problem arises when the impedance seen looking into the ladder-line is high because it is difficult to get enough choking impedance. That's one reason I feed my antenna systems at a current maximum point.

Reg, I'm sure if anyone applies engineering equations to your rules-of-thumb, they will find them adequate. Rules-of-thumb fine-tuned over many trials are often just as good as engineered designs and sometimes better if the engineer ignored an important parameter or two.

I've measured some of them and they tend to have a low
impedance/cost ratio compared to a single toroid with
multiple turns. (The square of the turns is more effective
when the turns don't equal one. :-)

No. Unless you have overload or signal transfer problems, a preselector
never helps.

The preselector may not hurt signal quality *if* you spend the time to
tune it carefully. On the other hand, it negates the most important
advantage that modern equipment has over the classic stuff: frequency
agility. With a modern receiver you can rapidly check propagation over a
wide range of frequencies, ID using parallel frequencies, find the best
parallel frequency for your favorite program *right now*, and jump to a
different one when interfence suddenly pops up. A preselector gets in the
way of all this. With interval signals on most stations reduced to less
than a minute these days, you don't have time to waste tuning in: you'll
miss the start of your program.

If local MW stations are an overload concern, a high pass filter is an
effective solution.

You've got to find the signal to hear it. Once you've found it, a
preselector may not hurt, but it definitely gets in the way of finding it.

Hi,

You need to change the length of the whip and most important,
remove the matching coil and replace it with the proper type.
The antenna is not built for 146 Mhz.

Try this link: http://www.cebik.com

Got to technicals page, page down to 2meter antenna
find half square for 2 m.

You can build the for $5.00 or less, uses coax feed,
no matching needed.

You also could make a 1/4 wave antenna with a so239
connector and some copper wire but the above half sq.
is better in gain and directional.

Give it a try.

Whether they do or don't, let's say samples looked OK. In any case,
if the first shipment was bad, the second shipment should have NEVER
been bad, since upon replacing bad cable they should have hand checked
every inch of the replacement, to ensure that there wouldn't be a
problem.

The main issue is not that the first shipment was bad, but that the
second shipment was bad, too.

I'll agree, but I wouldn't limit it to advice from salesmen.

I got into this thread when someone gave what seemed like an overly broad endorsement of preselectors.

I'm sure the person who made that post has had great luck with preselectors, as they do serve a purpose. On the other hand, if you don't have the problems they're designed to solve, they won't help you.

Actually, I have come to realize that is less than a turn. To be one turn,
as defined by Amidon, the wire needs to form a 360 degree loop with
one wire through the core. The difference between a straight-through
wire and one 360 degree loop is considerable.

That's exactly correct. Except that depending on the core type and frequency, the impedance can be more resistive than inductive. But the impedance, regardless of angle, follows the same rule of increasing as the square of the number of turns.

A sufficiently low value is one which is low enough that you don't have whatever problems you're intending the balun to prevent. If you don't know what some of these could be, I suggest taking a look at "Baluns: What They Do and How They Do It" in the ARRL Antenna Compendium, Vol. 1. You know you've got it when the problems are cured. This is the same basic approach I take to all engineering problems.

I think people like the W2DU type balun because of its ease of construction and mechanical simplicity. This seems true particularly of people running high power. At levels of up to a couple of hundred watts, you can wind a few turns of RG-174 on a ferrite toroid and have an excellent all-band balun, and that's what I do. But the RG-8 crowd can't do this. To make a balun with a toroid, they have to use parallel wires with good insulation. I'm not sure it's necessary, but Sevick uses such materials as Teflon tubing and tape in some of the designs in _Transmission Line Transformers_. Some people would understandably rather throw some money at the problem and slip some beads over an existing RG-8 size feedline to have a balun in a minute or two rather than scrounge up the materials for a toroid balun, figure out a way to mount it, weatherproof it, and apply connectors. I don't use W2DU baluns myself because I don't need to, but I understand their appeal.

I would expect that but I haven`t measured it. I do believe displacement current completes many circuits containing no physical circuit. The current amplitude and core excitation are probably reduced by capacitive reactance in the displacement path.

You might try a horizontal loop. I have had reasonable luck with a 15 meter full wave loop (about 11 ft per side) mounted horizontally in my attic. It is corner fed with coax. It works better than I thought it would on 15. With a tuner it is not too bad on 10, and is a little worse on 20. However, the price is right.

One additional item. My antenna fried the electronic thermostat for the furnace, since there was a lot of coupling from the antenna to house wiring. On the new thermostat, I used a toroid to keep RF from coming into the box.

>wire and one 360 degree loop is considerable.

Hi Cecil,

Shame on you. A toroid with ANY conductor through it has satisfied
the one turn requirement and this simply because it is not a
requirement. The physics of it is that a flux line must be broken by
the media, there is no 360, 350, 180, or 90 degree requirement. This
was rendered into core memory decades ago without any ambiguities of
partial turns.

There are other reasons for having the shortest length for the turn
like absolute inductance, coupling and leakage (presuming there are
more than one turn), but these reasons are not numerically related to
"complete" turns.

In the literature of transformers (both BALUNs and standard power
supply cores) there is no such thing as a partial turn except as
expressed as a ratio such as 2:1.5 which could only be realized by,
for instance, 4 turns (or wire penetrations of the core) seeing 3
turns (or wire penetrations of the core). I would like to see an
argument (not a fantasy) that supports that this could also be
satisfied with 2 turns seeing 1.5 turns - in other words, for a toroid
show me the math and your references. I would be most interested in a
mathematical solution expressed with a non-integral number of turns.

Jim Lill wrote:
"I am still looking for the angle on the bowtie (flat planar type)."

I gave you the angle in an example from Arnold Bailey`s "TV And Other Receiving Antennas". The projected angle was 60 degrees. That will do for flat bowties too. I`ve seen examples that had angles between 40 degrees and 60 degrees, but it isn`t critical.

On page 657 of Henney`s "Radio Engineering Handbook" is Fig. 36-o. This is a flat bowtie. I don`t have a protractor, but the sides of the triangular halves of the dipole form near equilateral triangles. That would make the angles 60 degrees each. On very close scrutiny, the angles at the feedpoint might be a couple of degrees or less larger than the the other two angles.

Here is what Henney (actually Ed Laport was the author of the antenna section of the book) says: "Figure 36-n is an example of a dipole, capable of many variations, where linear conductors are replaced by plane sheets of selected shapes for obtaining special characteristics.

In all of these forms of electric dipoles, bandwidth can be increased by increasing the radiator cross section when the application is associated with wide-band systems."

Source record: 170663

IIRC there was an article, years ago, about using one as
a 5/8 wave antenna on 2m. It involved pulling off the coil
cover and stretching the coil (I think!)

Trouble is - as I found out) not all of them can have the
coil cover slipped off easily as some are moulded right
on to the coil and you run the risk of ruining the whole deal.

The one here that worked was from RShack and had a grey
fluted coil cover. Lots of help. I know. I know! :-)

I don`t claim to be any of the above but offered an opinion anyway. I said a 1/4-wave coax grounded at the bottom would offer a high impedance to current feed from the inside to the outside surface of the coax at the top.

On Thu. Feb. 8, 2001, 8:43am Central U.S. time I wrote:
"Reg already suggested using a 1/4-wave (or odd multiples thereof) for a feedline, and making sure there was a good ground on the radio."

I presumed why this would be beneficial would be understood, given the discussion of baluns.

Hi Reg--

> If the coax feeder is 1/4-wavelength long and the braid is properly grounded at the bottom end there will be a very high impedance at the top and very little current will flow into the braid.<

Is your Guiness going flat? Who on here HASN'T acknowleged that ("properly" being the operant term).

> Will this prevent radiation from the feeder just as the choke balun is intended to do?<

Of course and your point well taken. It's still a matter of critical timing vs. who-the-hell-cares feedline length (or an academic point vs. real-world engneering practice).

>Why have none of the experts, antenna designers, and old wives answered this question ? Its been here for several days.<

Don't be petulant! My kW station sits atop a glacial sand moraine, not a moist black-dirt UK garden-spot. Do you really think those two entities rest at the same potential? The local turf has the conductivity of fine chinaware.

That bumper sticker is the reverse of one I received from Spruill Chevrolet 10 years ago. The original was "Friends Don't Let Friends Drive Fords".

Just as an aside, I left Ford in 1973 never to return for 2 reasons:

1. My 1972 Mustang kept causing me to be "Found on Road DEAD" and it taught me how to spell F-O-R_D backwards: Driver Returning On Foot!

2. Engine noise difficult to cure. We used to listen to the AM broadcast radio and you could tell there was a Ford passing by due to the noise in the receiver. No LIE!

I quickly returned to Chevrolet where I found reliable transport AND I often could install an HF radio without doing ANYTHING about ignition noise! Just today, I finally got around to installing an Icom 706 MKIIG in my 1993 Lumina Z34. NO ignition noise, no "funny" effects on the ECM, and receiver as quiet as a mouse except for the atmospheric noise inherent to HF frequencies. I NEVER had a Ford like that. They ALWAYS had so much ignition buzz, the radio was almost unusable without a few hours spent curing the blasted thing. My other car is a 1987 Chevy Celebrity wagon I bought new. It now has 199,000+ miles on it and still runs fine. Engine/tranny has NEVER had a major failure, never has been opened, only has had routine maintenance. I have had an HF radio in it since new. Again, NO noise! I just installed the radio and did the usual grounding.

Now let me see: What vehicle is mentioned on the radio newsgroups more than any other for ignition/fuel pump interference? If you guessed FORD you are right! Just my opinion, of course, but I'll take a Chevy/GMC any day over a Ford!

> Cecil, waffle, waffle, in other words, you don't know.

I know for my antenna system, Reg, because I designed it that way.
I don't know for yours. If you can wind a near-lossless balun with
negligible impedance to differential currents and with a megohm of
reactance to common-mode currents then it will work with almost any
antenna system.

The required choking impedance depends on the antenna system design.
It is impossible to design a balun for some antenna systems. I
design my antenna systems so the balun is easy to design, i.e. my
balun always works into a resistive impedance between 25 ohms and
100 ohms.

Good example of how the fastest way to success is through failure. :)
Our culture is so focused on winning and success that we forget

that failure can be the best and fastest teacher, if you're able
to set aside your ego and and really learn *why* you/it failed.
If it makes you feel better, don't call it a "failure", call it a
"prototype." :)

I thought so too, Richard, until I measured it. Let's say we have a
toroid with a one inch by one inch cross section. A 360 degree loop
is in contact with the toroid for five inches. A straight through run
is in contact with the toroid for one inch. Exposing the field to
five inches of ferrite apparently has a greater effect than exposing the
field to one inch of ferrite. The FB-77-1024 core does not meet the
inductance spec unless a 360 degree loop is used. I know, I tested it
and was amazed that conventional wisdom, as I understood it, was wrong.

Another way to look at it: if you're tuned into a strong signal,
reducing the RF gain reduces the accompanying static, but leaves the
stong signal sounding nicer. At least, that is my practical
experience.

Some do. It is possible to purchase certified coax, in any length you desire. Of course you pay a nice premium for it.

I believe Andrews is one of the suppliers who will do so. You could check their web page to see if there is any mention there.

But this is only a test of the electrical characteristics - not for such problems as slits or holes in the outer covering.

The issue is the TYPE of tinted glass, Randon. You cannot use a glass-mount antenna with passivated glass that has been impregnated with metal (plain tinted glass works fine with these antennas).

How can you tell the difference between normal tinted glass and passivated glass? Look around the edge of the glass for the manufacturer's stamp. Once you locate it, look for words that have to do with ultraviolet rays or the sun (solar, solarglare, solarclear, solarcool, sunshield, sunscreen, soft-ray, eze-cool, or similar words). If you find such words, you probably cannot use a glass-mount with this metal impregnated passivated glass.

If you want to be absolutely sure, you can always test the glass with a capacitance meter, or have someone else (radio or cellphone store) check the glass for you.

Luckily, on most vehicles, it is only the lightly tinted windshield and two tinted front windows (driver and passenger) that have passivated glass - the darker tinted windows in the rear of the vehicle are usually made of cheaper, not passivated, glass.

By the way, if any glass on your vehicle is passivated, the windshield almost certainly will be also, even if it doesn't specifically say so (some manufacturer's don't stamp the windshield for some reason).

My '96 GMC1500 pickup is the RF quietest vehicle I have ever owned.
I can hardly tell by listening to my IC706 when I shut the engine off.
Only problem is when I key up on 40m, the speedometer goes full scale.

2807. What is antenna resonance?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-09 04:53:13 UTC
From: jason_hsu@my-deja.com
Message-ID: <95vt3n$48h$1@nnrp1.deja.com>
Source record: 170580

I realize that this is a dumb newbie question, but I don't fully understand antenna resonance.

I know that is issue is separate from SWR, as SWR only applies to the impedance match between the antenna and transceiver. I know that you can have a low SWR in spite of a nonresonant antenna (because the radiation, ground, and conductive resistance of the antenna add up to 50 ohms) or a high SWR in spite of a resonant antenna (like a 1/2 wavelength vertical antenna without the appropriate matching for the stratospheric antenna resistance).

Does antenna resonance affect radiation resistance and thus affect antenna efficiency? Exactly what happens when you try to transmit on 10m with an antenna resonant for 20m? Or vice versa? Is there a measurement for resonance analogous to antenna efficiency or SWR?

Can anyone explain this concept for me? I know the formulas, but I don't have a grasp of it.

Currently have a Diamond Dualbander VHF on roof 19' tall. I am getting ready to mount a butternut hf9v up there also. They will be about 8-10' apart. any thoughts on interaction?. Will have the radials up there to.

Depends on the earth qualities. If the earth is poor, your actual reflection may be quite a ways below the surface of the earth and traveling though a lossy medium. Not too good. With radials you are controling the ground losses, which you must do if you want the 1/4 antenna to have the efficiency near what you would have with a 1/2 wave antenna.

> 2. If the antenna is shortened through loading schemes (capacity hats,
> loading coils, etc.), is the size of the ground plane required also
> smaller? Does a shorter antenna have a different near-field and far-
> field radiation pattern than a full size antenna?

Some say you only need the radials as long as the radiator, but I'd rather still have 1/4 wave or longer radials if I had my choice. If you don't have much wire, it's better to concentrate at the base with more short radials than a few long ones. But if I had many of them, I'd just as soon they be full length. If the antenna is elevated, they must be kept at the same 1/4 wave length. Or at least be a length to show a low impedance at the frequency being used. I've used 3/4 wave radials before. They need to be resonant to work properly. The ground system becomes more critical the shorter the antenna. As usual, no free lunch..:(If you try to skimp with a shorter radiator, you have to make up for it in the radial system if you want near equal performance. The ground losses will overshadow the coil losses usually.

> 3. How exactly does ground conductivity matter? It seems to me that
> there would be a VERY high resistance between the antenna and a point
> in the far field of the antenna.

We pondered this a few weeks ago. Seems to me being we can't do much about the ground conductivity at a distance, not really much use worrying about it. The main effect of lossy earth being a cancellation of the lower angles. I can only control whats in my yard. Much of what you want to know you would be better off to find a few good books to look at. There is much more to all this than can be covered in NG posts.

Dunno, but I kind of think the preselectors get a bad name when used with preamps. IE: "active preselectors and antennas". Some of these can use quite a bit of gain and can trash the front end of an already good receiver. But seems to me a preselector used on it's own should be ok. Or at least , shouldn't really hurt anything, and normally should help if an outside signal is a problem. But I don't think the s/n ratio would change much unless the preselector was curing an outside signal problem. If the undesired signal quit, there shouldn't be much difference. I don't use any here, except for the ones built into some of my radios. IE: TS830, drake receivers etc which use a preselector control. I found out a long time ago on the drakes, the quickest way to trash one out was add a 20 db preamp. I once made one to try it. It worked fine, but ruined the receiver overall. Too many images etc. And it didn't help the s/n ratio at all really. Just pumped up the s meter. MK

They will interact. Enough to be a problem? Maybe, maybe not. Depends on
the band used. Most bands you probably will be ok. You might try
grounding the unused one if a problem comes up. MK

> Does antenna resonance affect radiation resistance and thus affect
> antenna efficiency?

No. Not the way I see it. Resonance of the antenna has little to do with efficiency. But! Many times some of the easiest ways to have an efficient system with the commmon feedlines used these days is with a resonant antenna. But thats not the antennas fault, but rather the feedlines we use just happening to have about the same impedance of a dipole for instance. It's hard to beat the efficiency of a dipole fed with good coax. It has more loss than ladder line, but needs no tuner and the tuner losses that go along to work with a 1/2 wave dipole.

Exactly what happens when you try to transmit on
> 10m with an antenna resonant for 20m? Or vice versa? Is there a
> measurement for resonance analogous to antenna efficiency or SWR?

A 20m dipole on 10m will be two half waves in phase and has a high feed impedance about the same as the 1/2 wl vertical you mentioned. This antenna is very efficient as long as you don't waste power in the feedline before it gets to the antenna. The efficiency is more feeding related than resonance. The antenna has gain over a dipole. "about 1.5 -2 db worth broadside". But it won't have gain over anything except a dummy load if you turn the rf into heat in the feedline as in would be the case doing this using coax.
A 10m dipole used on 20m will show a large capacitive reactance. Again, if you can get power to the antenna, it will be quite efficient. But usually in most cases you will turn much rf into heat in the tuner used to match such a setup. Or at least when using ladder line and the common T net tuners. You can get a coil quite warm doing this with high power.

Hummm, some of my most reliable cars have been fords. But then again I have had reliable chevy's, and mopars too. I have a 68 ford F250 I drive the most these days. It's quite reliable with it's old 300 six and 4 speed. But I also have a chevy monte carlo which has never left me standed once yet. So for me, both have been ok. I had a 1960 ford falcon that was like a timex. You couldn't kill that car. Also had a 1967 LTD with a 390 that was fairly bulletproof. But I do have to say, some of the new ford stuff has been kinda funky. Some of the transmissions are junk for one thing. IE: mustangs,tauruses, etc, had alot of these problems.

My chevy is pretty quiet radio wise. I just recently installed the mobile setup on the ford, and seems ok so far. A little ignition noise, but I think I can filter that out. It's not too bad. Or at least hasn't kept me from talking. I put new wires on it not too long ago. Probably need a filter kit. Being a 68, it has points, not solid state ignition. I mounted my antenna right behind the back window in the center of the truck. Seems to work pretty well. I've tried it on 75 and 40 meters and was doing fine. I'm also using a 706G now. I had to retire my trusty 730. Or at least until I can find a basket case to get the part I need.

Right Mark, most of the Black Boxes now sport a step attenuator in the front end to attenuate the noise, most of which is due to the extremely wide pass band of their front ends.
The cost of providing a proper preselector in the I/P circuit to the Receiver would not only raise the selling price of the set above the ideal market price the penalty in box volume would probably also be unacceptable.

Consider this for one of the top line RX
Only the names have been changed to protect the innocent. :)
This is fairly typical of what you can readily buy today.

Table 1
| RX I/P bandwidth
| f lo | f hi | BW | BW dB | Av f | Q
1 | 0.5 | 1.6 | 1,100,000 Hz | 60.4 dB | 1,050,000 Hz | 0.955
2 | 1.6 | 2.5 | 900,000 Hz | 59.5 dB | 2,050,000 Hz | 2.278
3 | 2.5 | 3.5 | 1,000,000 Hz | 60.0 dB | 3,000,000 Hz | 3.000
4 | 3.5 | 5.5 | 2,000,000 Hz | 63.0 dB | 4,500,000 Hz | 2.250
5 | 5.5 | 7.5 | 2,000,000 Hz | 63.0 dB | 6,500,000 Hz | 3.250
6 | 7.5 | 10.5 | 3,000,000 Hz | 64.8 dB | 9,000,000 Hz | 3.000
7 | 10.5 | 14.5 | 4,000,000 Hz | 66.0 dB | 12,500,000 Hz | 3.125
8 | 14.5 | 21.5 | 7,000,000 Hz | 68.5 dB | 18,000,000 Hz | 2.571
8 | | | | | |
9 | 21.5 | 30 | 8,500,000 Hz | 69.3 dB | 25,750,000 Hz | 3.029
9 | | | | | |

Table 2
| -.. ..--- . .-.. .-.. HAM BANDS -.. ..--- . .-.. .-.. |
| f lo | f hi | BW | BW dB | Av f | Q
1 |
2 | 1.8 | 2 | 200,000 Hz | 53.0 dB | 1,900,000 Hz | 9.5
3 | | | | | |
4 | 3.5 | 3.8 | 300,000 Hz | 54.8 dB | 3,650,000 Hz | 12.2
5 | 7 | 7.1 | 100,000 Hz | 50.0 dB | 7,050,000 Hz | 70.5
6 | 10.1 | 10.15 | 50,000 Hz | 47.0 dB | 10,125,000 Hz | 202.5
7 | 14 | 14.35 | 350,000 Hz | 55.4 dB | 14,175,000 Hz | 40.5
8 | 18.068 | 18.168 | 100,000 Hz | 50.0 dB | 18,118,000 Hz | 181.2
8 | 21| 21.45 | 450,000 Hz | 56.5 dB | 21,225,000 Hz | 47.2
9 | 24.89 | 24.99 | 100,000 Hz | 50.0 dB | 24,940,000 Hz | 249.4
9 | 28 | 29.7 | 1,700,000 Hz | 62.3 dB | 28,850,000 Hz | 17.0

Table 3
| Degradation
|
2 | 6.5 dB
|
4 | 8.2 dB
5 | 13.0 dB
6 | 17.8 dB
7 | 10.6 dB
8 | 18.5 dB
8 | 11.9 dB
9 | 19.3 dB
9 | 7.0 dB

The first table shows the I/P filter Bandwidth
The second table outlines the HF Ham Bands
The third table shows the degradation of the I/P noise bandwidth.

Note that on 18 MHz and 24 Mhz the excess noise at the front end is nearly
20 dB over what it would be if you had an Rx specially designed to just
cover those Ham bands.
No wonder that you require a pad at the front end.
Having struggled to get the gain you then throw it away. :(

You will notice the effect if you listen to 20 m regularly that there are
some days when you might think that the band is dead, absolutely flat.

You put in 10 or 20 dB of attenuation and there are plenty of signals on
the band.

The Rx has been completely overloaded by the noise available in the
extended/excessive bandwidth of a general coverage Rx compared to a Rx
specifically designed for Ham bands only.

When I say noise in this context I include any signals that you do not wish
to listen to.
i.e. strong short-wave broadcast transmissions, strong machine
transmissions, any strong signal that can contribute power to the front end

semiconductors.

noise is the weeds of Radio ... REM is that grammatical?
weed: any plant that you do not want.

Of course adding a pad reduces the excess noise, but it also reduces the signals that you would like to listen to.
The use of a tuneable filter that can be set up around the segment of the spectrum that you are interested in will reject the excess noise *without* attenuating the wanted signals by more than a dB (provided the filter is correctly designed and tuned.)
Looking at row 7 in each table which covers the 20 m band there is a possible 10.6 dB to be gained by using a preselection AE filter.

If you are only interested in say the Machine sector of 20 m then there is even more to be gained from a bandpass filter directly at the AE.

In this context using a filter is like using a selective weed killer, using an attenuator is analogous to using a flame thrower.

Well! that goes without saying to anyone that knows why they have bought and
fitted such a device. duh!

>On the other hand, it negates the most important
> advantage that modern equipment has over the classic stuff: frequency
> agility.

Which is a fat lot of use if you can't actually hear anything.
What about all that good DX below S1 that is perfectly readable once you
clean up the noise and out of band interfering signals [QRM]

>With a modern receiver you can rapidly check propagation over a
> wide range of frequencies,

Not if you can't hear the weak signals because they are drowned out by
excess noise and out of band strong signals.

> ID using parallel frequencies, find the best
> parallel frequency for your favorite program *right now*, and jump to a
> different one when interfence suddenly pops up. A preselector gets in the

> than a minute these days, you don't have time to waste tuning in: you'll
> miss the start of your program.

You are talking 30 dB communication margins, not typical threshold DX
working that most Hams will really be interested in. Why don't you just buy
a mobile phone instead, that way you can also have selective calling.

> If local MW stations are an overload concern, a high pass filter is an
> effective solution.

That is certainly a very good measure. However it is not only MW broadcast
that is a problem, any strong broadcast station will cause problems,
suddenly populating the ham bands with all sorts of wonderful signals. ;(

> You've got to find the signal to hear it. Once you've found it, a
> preselector may not hurt, but it definitely gets in the way of finding it.

You certainly won't find it if it is:
a. below the noise
b. attenuated out of existence.

Theorecitally you could cut a small square in the tint the size of the
capacitive coupler,
this is the part that attaches to the inside of the window.
But like the other gentleman said if you special impregnated glass it would
work to no avail anyway.
Thru-glass antennas are not very efficient nor is any other antenna that
uses
a capacitive coupling such as a magnet mount.
If youre serious about the system i would suggest doing what other vette
owners do,
attach a piece of flat bar or angle iron to the frame (the frame is the
counterpoise)
that extends beyond the rear of the car and attach the antenna there.
The Firestik antenna company has a Corvette section just for people like
you.
http://www.firestik.com

2818. Re: What is antenna resonance?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-09 11:45:25 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <960l6g$8qc$1@neptunium.btinternet.com>
Source record: 170591

It's not a dumb question. It's probably the best question to ask about antennas.

Any length of wire, straight or bent, has inductance L and capacitance C. L and C are distributed along the length but have equivalent lumped values.

Using lumped values, think of a dipole antenna as an inductance and a capacitance and a resistance R all in series across a voltage generator. (The end of a transmission line from the transmitter). The resistance is the radiation resistance. Behaviour is similar to any other LCR tuned circuit.

Inductive reactance increases with frequency. Capacitative reactance decreases.

The antenna is at resonance at the frequency where the capacitative and inductive reactances are equal and cancel out. The impedance across the generator is then at a minimum and is equal to the radiation resistance. The antenna current is at a maximum.

The input impedance changes rapidly with frequency but the radiation resistance remains fairly constant. As with any other tuned circuit the sharpness of tuning depends on Q, the ratio of inductive reactance to resistance. Q = XL/R and for a full size HF half-wave dipole Q is between 6 and 10.

Because L and C are actually distributed along the wire length there are many resonant frequencies known as harmonics. These are related to the fundamental in the ratios 2/1, 3/1, 4/1 . . . . etc.

An antenna will still radiate highly efficiently when driven at a frequency way off resonance. Practically all the power which is fed into it will be radiated. Input power has nowhere to go except out into the universe. Only for very short antennas is the radiation resistance less than the wire resistance.

The only problem with non-resonant antennas, because of their high input reactance, is getting them to accept power. It is necessary either to insert a voltage step-up transformer between generator and antenna, or tune out the high input reactance with another lumped component, L or C. Or there may be several variable components in the form of an L, T or Pi network to cover several frequency bands. It is the loss in the transmission line and tuning components which may give cause for concern.

SWR measurements are made to check that the resistive load on the transmitter is at the value it was designed for, usually 50-ohms.

chinaware.

At my last QTH the sandy soil was 2 mS. At my present QTH the garden dirt is around 20 mS. I can manage quite well with no more than a half dozen short radials.

But chinaware is a pretty good insulator. Your ground losses are probably less then mine.

Jason:

Resonance and resonant frequency is a widespread physical phenomena which applies to many areas of mechanics, dynamics, and physics, including antennas.

Resonant frequency is the "natural" frequency of vibration of something. i.e. the resonant frequency of a guitar string is the natural frequency at which it vibrates when you pick it. The resonant frequency of an LC tank is the natural frequency at which electrons "vibrate" or slosh back and forth between the L and the C when it is "hit" by an electrical impulse. The resonant frequency of an antenna [a distributed electrical structure] is the natural frequency at which electrons will "slosh" back and forth from "end to end" when it is hit by an electrical impulse.

Now any physical system, guitar string, LC tank, antenna, etc... can be made to vibrate at frequencies other than its' natural or resonant frequency. With a transmitter driving it, one can readily "drive" electrons to slosh back and forth on an antenna structure at any frequency, not just at it's resonant frequency. "It's just a little more tricky to drive or "force" a system to vibrate at frequencies other than it's natural or resonant frequency.

And so a "resonant" antenna is one that is being driven at it's resonant frequency or natural frequency of vibration.

This resonance phenomenal has very little to do with the radiation efficiency of an antenna. Or with the energy storage capability of any system capable of vibration. Systems that vibrate, are simply systems that are temporarily storing energy in different forms between in cycles. i.e. on one portion of the cycle the energy is in kinetic form and on the next portion of the cycle the energy is in potential form, and the process repeats continuously even at frequencies far from resonance if so driven.

Radiation is not a function of the frequency of vibration per se, but rather is caused by the acceleration and deceleration of electric charges. i.e. the change in velocity of those charges, not the actual frequency of vibration.

Radiant energy or RF is given off, and so extracts some small fraction of the stored energy, whenever electric charges are accelerated or decelerated. An antenna can easily be made to radiate energy efficiently when the electrons on the antenna structure are driven to slosh back and forth at frequencies offset from its' natural or resonant frequency. i.e. the non-resonant antenna can be made to radiate just as well as the resonant antenna. All you have to do is cause acceleration and deceleration of the

electrons. Radiation will occur because of the accleration and deceleration regardless of the frequency of "sloshing" back and forth. The electrons sloshing back and forth, at whatever frequency, on the antenna structure will radiate simply because they are being accelerated and decelerated. Now one has to admit that, coaxing those electrons to slosh at other than their natural sloshing frequency requires some additional techniques, i.e. feed line matching, etc...

Whether an antenna is operated at resonance or not is simply a function of the way in which you try to "force" or drive the antenna's electrons to slosh back and forth. Once the electrons are made to "slosh" back and forth on the antenna structure, their accelerations will result in radiant energy even if it is not the "natural" or un-driven frequency of sloshing!

In other words, the feeding method, feedline impedance, use of antenna tuner, etc... will require some attention if you operate "off resonance", while "on resonance" less attention needs to be paid to the driving of the vibrations. Just as with anything that is capable of vibrating, you can "coax" an antenna to vibrate at almost any frequency with the appropriate "driving" method...

And so... a "resonant" antenna is one that is operated at it's natural frequency, while a non-resonant antenna is not. Resonant or not has very little, if anything, to do with radiation efficiency.

> For example, Sqrt(50*450) = 150 ohms.

Yes, but most 450 ohm line carries a high SWR. So the two terminations
are NOT 50 and 450 ohms. With a high SWR, it is guaranteed that the
impedance looking into the 450 ohm feedline will NOT be 450 ohms.

I design my systems so the second impedance termination is between 25
and 100 ohms, closer to 50 ohms than anything else. Thus, for my antenna
system designs, the Z0 of the feedline used for winding the choke should
be close to SQRT(50*50) = 50 ohms.

The antenna itself is often not resonant and does not need to be. It is the total "system" that is resonant. For example, suppose the xmtr sees a pure 50 + j0 ohms looking into the coax. The system is resonant, even if the system has moderate losses. The system includes impedance transforming LC networks, lumped and linear. There are no reactive volt-amperes being delivered to the coax and there are no reflections at the sending end of the coax. The radiated power is maximum.

Correction:

The correct resistance may be some value other than 50 ohms, but the reactance is zero. There may be a reflection on the line, causing the input resistance to be other than 50 ohms, but if it pure resistance then the system is resonant and radiation is max, if the xmtr can deliver the prescribed watts to that value of resistance.

Source record: 170600

I have gotten a used KLM (I am told) 2m beam from a friend, but have no documentation. The boom is about 23 feet long; there are 11 passive elements made of small diameter aluminum rod. There are 2 active elements made of aluminum tubing with some sort of phasing (small diamter coax loop and aluminum strips) between them.

I'm looking for identification, and if possible documentation on this antenna. One of the passive elements is broken, but it shouldn't be too hard to find replacement rod. The insulators that hold the driven elements are broken and need to be replaced. With KLM out of business, is there any chance of finding replacements? If not, I don't think it would be too hard to fabricate something, but I'd like the documentation to see how everything is supposed to go together.

Richard Clark wrote:
"A toroid with ANY conductor through it has satisfied the one turn requirement and this is simply because there isn`t a requirement."

That`s right. We remember the memory cores most computers used in the beginning with their myriad of tiny doughnuts having a criss-cross of wires strung through them, each making a single pass. It took a sum of excitations for enough magnetizing force to flip the polarity of a core.

But, Cecil measured reaction from passing a wire straight through a toroid as opposed to wrapping it around a toroid. The wrap produced a bigger reaction. The wrap must have been better coupled to the core.

We use clamp-on a-c ammeters and know to split the wires apart and clamp around one or the other. It`s calibrated that way and we have a complete conductive circuit with all parts located well within a tiny fraction of a wavelength.

B. Whitfield Griffith, Jr. says in "Radio-Electronic Transmission Fundamentals":
Figure 27-6 shows a conductor which passes through a metal ring. Current flows in the ring in the direction indicated by the current arrows, and the total value of this current over the entire circumference of the ring is equal to the current in the conductor. The direction in which the current in the ring is flowing is known as the "toroidal" direction; a toroid is something shaped like the surface of a doughnut.

Radio-frequency currents naturally tend to follow the path which has the lowest inductive reactance. For this reason, the "going" and "return" currents tend to stay as close to each other as possible, so that the loop around which the current flows encloses the smallest possible area."

The above means a wire straight through a toroid can impart or receive the energy to or from the core. Wrapping around may actually increase the exchange. I wonder if the first complete turn around a core is more effective than subsequent turns?

Jason:

These are excellent questions!

As many have already stated, an antenna is resonant when the reactive component of its feedpoint or input impedance is zero. In this case, the antenna feedpoint impedance is purely resistive. A linear dipole will have many resonant frequency points if you measure or calculate impedance as a function of frequency. In a free space situation, a linear dipole will exhibit its first resonant frequency at a point where the dipole is approximately 1/2 wavelength long. Theoretically, its resonant resistance would be approximately 73 ohms. If you were to increase the operating frequency, there would be other resonant frequency points but the resonant resistance would be much higher.

Your statement on SWR is correct, SWR is simply a measure of the impedance mismatch of the antenna feedpoint impedance with respect to the characteristic impedance of the feedline.

> http://www.deja.com/

The antenna resonance does not "affect" the antenna efficiency. The antenna efficiency is a function of the loss in the antenna structure. Efficiency can be determined from knowing the antenna's radiation resistance and its loss resistance, both determined at the antenna feedpoint. The total feedpoint resistance is equal to the radiation resistance plus the loss resistance. The total power delivered to an antenna is a direct function of the antenna's feedpoint impedance8: Power = |I|^2 R. Knowing the total feedpoint resistance (Rt) and the total feedpoint radiation resistance (Rr), the efficiency is simply equal to Rr/Rt. The power delivered to Rr is the power radiated Pr = |I|^2 Rr. A dipole antenna near 1/2 wavelength long will have a radiation efficiency (Pradiated/Pdelivered) near 95 - 98%. As the operating frequency is lowered, the antenna becomes smaller wrt the wavelength and the total feedpoint resistance decreases and the feedpoint reactance increases. This significantly increases the impedance mismatch between the feedline and the antenna making power delivery to the antenna a problem. Less total power is delivered to the antenna as SWR increases, assuming the total forward power arriving at the antenna remains constant. At the same time, as frequency is lowered, the loss resistance becomes a larger component of the total feedpoint resistance and the antenna efficiency decreases. These two factors are the significant problems with reducing antenna size: Delivering power to the antenna becomes a problem while at the same time, radiation efficiency decreases.

Jason Hsu wrote:
"I don`t fully understand resonance."

We all have knowledge gaps.

Zero reactance, that is a balance between an antenna`s inductance and its capacitance, is resonance.

An antenna`s resonance depends on its size, configuration, and environment.

SWR is due to reflected energy. A matched dummy load produces no reflection. There are traveling-wave antennas (usually long) which do their things on the way to and from a dummy load, and these usually have no standing waves.

A 1/2-wavelength antenna has a large SWR on the antenna itself. The wave fed the antenna exhausts its guiding conductor at its end before the wave itself is exhausted. There is energy remaining in the incident wave to be reflected as a return wave. The interaction of incident and reflected waves produces a standing wave on the antenna as it would on a transmission line. Hopefully the loss of energy to free-space is larger in the antenna than in a transmission line.

Confirmation of the conditions causing SWR is had from the impedance variations at the antenna drivepoint caused by modifications at the open-circuit ends of the antenna.

SWR on the antenna is more a phenomenon than a problem for solution. SWR on a transmission line is a problem we might like to manage.

Conductive (copper loss) resistance in an antenna is rarely a problem, even if the conductor may be a steel tower. Loss resistance should be small as compared with the radiation resoistance. Ground return loss can be a big loser, but should be made small by design. The power fed to an antenna is spent on useful load and losses in proportion to their resistances. Keep the losses low.

An end-fed 1/2-wave antenna has a high drivepoint resistance. Whether it has reactance or not depends on whether it is really resonant.

!/2-wave is not the only resonant length. There are any number of frequencies of resonance for the same piece of wire. They are harmonically related. At the lowest of these (and all the others) the reactance becomes zero at the feedpoint. This repeats at twice the frequency, three times the frequency, etc.

Electrically, a 1/4-wave and electrically, a !/2-wave are shorter in a wire than their physical free-space lengths. How much shorter depends on diameter to length ratio of the antenna wire, and to a phenomenon called end effect (due to that open-circuit at the wire-end, again). Ed Laport gives tables for shortening due to length to diameter ratio (his way is upside down for me) in "Radio Antenna Engineering".

Stratospheric antenna radiation resistance is not a world-shaking problem. It may be inconvenient, but a simple parallel resonant circuit can be designed to include the high-resistance radiator and do very well.

Feedpoint resistance is a tangential factor in antenna loss. The key point is the ratio between load resistance and loss resistance. Keep it big.

What happens when you transmit on twice the frequency an antenna was designed for? It depends on the original design. For sure, the radiation pattern will change, and unless the antenna is of the traveling-wave type, the drivepoint impedance will change too.

At a harmonic frequency an antenna may again be resonant, that is it has no reactance at its terminals. But, if a 1/4-wave vertical is to become a 1/2-wave vertical, it will need to be fed more voltage and less current to radiate the same power.

Best regards, Richard Harrison, KB5WZI

2833. Hamstick on Dodge Caravan

Newsgroup: rec.radio.amateur.antenna

From: dmensing@my-deja.com
Message-ID: <961a2b$9ij$1@nnrp1.deja.com>
Source record: 170606

I want to mount my Hamstick HF antenna on my 1995 Dodge Caravan and am looking for suggestions. As I see it there are 3 main choices:

(1) Attach a ball mount somewhere on the side of the van. (What is the best location for such a mount?)

(2) Use a multi magnet mount on the roof of the van. (This will put the antenna very high. Good for RX/TX, bad for bridges and trees.)

(3) Use a gutter mount. (Same plus and minus as (2) above.)

I am leaning towards (1) but am timid about drilling into the body of the van. Also, I'm really not sure of the best location for the ball mount. (Left or right side, high or low, toward the rear or further up the side of the van.)

I'd like to hear from anyone who has experience with HF antenna mounts on a Caravan.

Thanks, Dave, N2PSH

Mobile mag mount CB antennas are generally base loaded so you would have to extract the loading coil from the base and run the whip directly to the connector or feed line. The next thing you would have to do is trim it to 5/8, 1/2, or 1/4 wave for your design frequency (most broadband 2m antennas use 146.000 MHz). It is not an impossible job but messy if the base doesn't want to come apart easily. A more common conversion is CB to 10 meters. Here you only have to cut the antenna length down a bit.

Good Luck & 73

Best place for the ball mount would be dead center of the
top of the van.

Dave,
Another laternative would be to mount the Hamstick
on the rear bumper using a mast to get it above the roof
line. Not the 'best' way of doing it, but still a good
alternative. It would also give you some means of
adjusting how high above the van it extends...

Jason Hsu wrote:
"It seems to me that there would be a VERY high resistance between an antenna and a point in the far field of the antenna."

You recall that resistance through matter is equal to its length times its resistivity divided by its cross-sectional area.

The distance from an antenna is a radius. At high frequencies, the earth`s crust is only shallowly penetrated by a radio wave. Out to a certain radial distance the h-f conductor takes the form of a big pie crust centered around the antenna. The thickness is more or less uniform depending on some variation in soil conductivity within the crust.

As an approximation we can say that a circumference of constant depth grows at two times pi times the radius, this is the same as pi times the diameter. Our soil cross section grows at the rate of 2pi times the radius.

Our conductance is growing more than 6 times faster than the distance from our antenna. In a short distance, the measured resistance to any point at any distance from the antenna would be very nearly the same, no matter how far away. This is one reason you soon hit a point of diminishing returns in extending antenna ground radials.

Best regards, Richard Harrison, KB5WZI

Reg,

I am not in one of the listed categories, but the answer is no. That is, with or without a choke balun, tuning the outside of the feedline to be resonant at the driving frequency is asking for feedline radiation. Even with no current at the feedpoint end of the outside of the coax, any unbalanced fields on any part of the feedline will induce currents in the feedline and since it is resonant it will respond substantially. A more sensible arrangement is a choke balun and a nonresonant length feedline. If you really must feed your antenna your way, I would suggest an additional choke balun at the point where the coax is connected to your high quality ground.

Hi Cecil,

Whenever someone describes having empirical results that go against
"conventional wisdom," it is in fact the empirical method that was at
fault.

For instance, to get a full 360 Degree wrap "could" involve the wire
penetrating the core twice. And yes, this would alter the observed
(expected, but naively so) results AND support "conventional wisdom."
That is, if the wire's 360 path starts in passing through the core, it
necessarily must end passing through the core once again. If on the
other hand the pass through the core starts at the 180 degree mark
(rather than the 0 degree mark), there would be only one penetration
of the core. You have not elaborated enough detail for me to
distinguish between the two.

Hence, I must judge that the confounding of "conventional wisdom" runs
a 50% chance of being an example of "conventional wisdom" proven.
Empirical results do not in and of themselves constitute proof of
anything without examining the method. I have calibrated many
Standard Inductors used expressly for these applications. There is
very little variation in the results when they are correctly applied.
Can the quality of the results vary dramatically? Yes, and these are
perfect opportunities to learn how you failed to observe the
limitations and usage constraints. None of this presents a failure of
the "conventional wisdom" however.

Source record: 170614

Yes, you can rebuild a CB base loaded coil up to a two meter 5/8 wave antenna as descibed in many a handbook and the ARRL Publication "FM & Repeaters for the Radio Amateur."

It would only be a task for the real experimenter. I did one once and everything you change effects everything else. You use only the original coil form and whip, hoping the whip is long enough.

A much better bet would be to use a 6 meter base loaded quarter wave antenna. Many scanner and 6 meter 1/4 wave antennas will work as 5/8 - 3/4 wave on 2 meters with little or no mods. I found one once that worked both places without any changes... 6 and 2 meters sold as a scanner receive antenna from Antenna Specialists.

Hope that helps

cheers

My father wishes to use a longwire antenna for QRP HF operation. My understanding is that most of the RF is carried on the outer edge of the anteanna. If this wire is smashed down through a window sill, what will the effect be on his transmission? Also, are there any concerns about RF in the shack from this antenna? His ground will be a 15-20 foot wire to a 8-foot grounding rod.

Any unbalanced fields, as you say, on any part of the feedline will induce currents in the feedline.

It is clearly excitable at its resonant frequency but should be short on excitation. The feedline is cross-polarized to avoid interaction with the radiator already.

I never tried Reg`s proposition but would expect no problems. So, there will be some feedline re-radiation. How much? I wouldn`t expect enough to worry about. I base that opinion on using many dipoles driven directly with coax with no balun at all which worked perfectly for my purposes, no feedback, no r-f burns, no reduction in radio range of significance, no deleterious effects at all.

Here's what I said, Richard:

"... To be one turn, as defined by Amidon, the wire needs to form a
360 degree loop with one wire through the core. The difference between
a straight-through wire and one 360 degree loop is considerable."

> Hence, I must judge that the confounding of "conventional wisdom" runs
> a 50% chance of being an example of "conventional wisdom" proven.

Nope, read it again - "one wire through the core".

> None of this presents a failure of the "conventional wisdom" however.

I said it was a failure of conventional wisdom *as understood by me*.
Anybody want to perform the experiment and report back here?

With the 360 degree loop, five times as much wire is in contact with
the toroid as when the wire is run straight through. According to
my measurements, there is a difference. I used an FB-77-1024 core
in series with a 50 ohm resistor.

Hi

Does anyone have any tips on reducing interference on wefax reception. I am using an FRG-100, Wellbrook active loop antenna and WXSat. The antenna is connected using URM76 Low Capacitance cable. Wherever I position everything I seem to get a lot of interference. Could it be either the receiver not being up to it or the cable? I am new to all this so sorry if i'm being thick! Any help greatly appreciated.

A few months after I bought my '87 Chevy, my pastor bought an '87 Taurus. He had trouble from the git-go. My Chevy just kept going. He had trouble for the life of the car. I told him one day when he was telling me all the trouble he had had with his Ford to jack it up and put a Chevy under it. LOL! When he was about to trade/buy another car, I mentioned that my car had had NO problems nor had it stranded me EVER. I thought, as disgusted as he sounded, surely he wouldn't make the same mistake. He bought a '96 Taurus! LOL! Guess what happened. Two trannies, fuel pump, radiator leak and various other problems that left him walking. He said, well I guess you're gonna tell me 'I told you so'. I just shrugged my shoulders--what could I say? I just said to just look at my old Chevy--170,000+ (at that time) and still going. I don't *think* he'll make that mistake again. LOL!

Dave, use a trailer hitch and make a bracket to elevate the antenna's base
base to at least 1/2 way up the car body but away from it about 12 inches.
This would be easy to remove and leave no holes in the body. A fancy one
would even fold or tilt rearward to allow opening the rear door.

Reg:

Tsk, tsk Reg... there you go again, Cecil baiting!

I perceive that Cecil is a bit more of an engineer than your assesment. He messes about in the real world using the scientific method not simply imagination.

Perhaps unlike your own mathematical musings and algorithmic programming.

Perhaps within your "free" software you are simply adjusting the outputs of your programs to match some measurements, e.g a "table look up", and since the algorithms used by your programs are hidden from us mere mortals, those internal mathematical machinations perhaps really have no internal basis for our faith in their accuracy.

At least Cecil posts pictures of his antennas for us all to see, while you do not post the source code for your free programs. The uninitiated might be led to think that your programs are also the results of "imagination".

Sorry to be so iconoclastic, but... it's a valid question, how about sharing some of your programmed wisdom with us?

An engineer is a person who can do for a dollar [pound] what anyone one else would need 10 dollars to accomplish.

Now back to baluns...

I wonder, since in my prior posts on this thread wherein I was musing in a rambling fashion about current versus voltage baluns, I considered inductances, and capacitances, but no losses, either winding or core.

If one were to consider winding and core losses, in addition to inductances and capacitances, then what is the best design for a balun, two in hand or separate windings? Voltage or current balun, and why?

i.e. which design yeilds the highest common mode rejection, with the least power losses, per dollar [or pound] expended?

That's not what is happening, Reg. I very deliberately feed my antenna systems at a current maximum point while ensuring that the impedance seen at the current maximum point is neither too high nor too low. I will not use an antenna system with a system feedpoint impedance less than 25 ohms or greater than 100 ohms which limits my 50 ohm SWR to less than 2:1 and makes my balun/choke function easy to design.

I am the only ham I know of who goes to such lengths in using the approach I use. That approach has been reasoned out over many years. Please try to understand. Here's an email I received today and is a typical one of many.

****
I just read your article on the No Tuner antenna, and the chart for the current maximum points for ladder line was most interesting. I have not seen this presented this way before. Excellent. ... The length of the feeders and current relationship that you talk about is excellent. ... Very nice article, and the ladder line is the only way to go.

Hi guyz !
Do you have any idea or links about short, no longer than 5+5 meters,
multiband dipole to cover at least 10m and 20m ? The 10-15-20 solution is
better ... What about 10-12-15-17-20 ?
I want to use it indoor and sometime outdoor ...
I guess it gonna be dipole with traps or set of parallel dipols or some
wide-band dipole ...

Hi Cecil,

Your objections are well taken, and I offer my apologies for the
misread.

As I now see it, this is not an issue of turns completed in terms of
toroidal properties (the "conventional wisdom" of standard magnetic
linked transformer windings), but rather the loss mechanism of a
ferrite media acting as a resistive component of a Z finding. This,
of course, mimics the toroidal properties that are sensitive to turns
count (when we are trying to determine the L, and by extension Xl) in
that turn counts squared multiply the loss, but the variations you are
exploring are probably less in the L (and by extension the Xl) than
they are in the R.

You are still holding your cards too close to the vest, why don't you tell us what the values are for a straight wire v. complete turn wire? This time I made an effort to look at your postings and find no data. Is it in the standard R +/- jX format , or simply a Z? If simply the Z; then, yes, you do need others to conduct the experiment.

Human communications is surely strange. I would have bet that statement
was unambiguous. :-)

Because I ran the experiment about a year ago and I don't remember the
values. Seems the impedance ratio was about three to one. I'll try to
perform the measurements again this weekend and post the results.

Hi Cecil,

Measured testing:

Fair-Rite 2643540001
Height: 1.125 in.
OD: .5625 in.
ID: 0.25 in.
Frequency: 20 MHz
Test Loop Z: 0 + j18
Test Loop through core Z: 135 + j90

specie unknown:
Height: 0.285 in.
OD: .1.14 in.
ID: 0.74 in.
Frequency: 20 MHz
Test Loop Z: 0 + j18

Test Loop through core Z: 11.2 + j40
Modified Test Loop through core Z: 11.5 + j38

the "Test Loop" consisted of 4 in. of #12 copper wire on a test adapter (which presents a residual inductance). The stiff wire presented a stable physical reference for the first test. The length allowed for testing the two divergent core types while meeting the requirements of the first test.

I first tested for proximal effects by varying the distance between a loose wound conductor passing through the core, and the core ID. I did this with both samples.

I then tested for a tightly wound turn (as opposed to the very loosely turned one above) using a shorter length of #16 copper wire for the second sample.

The results indicate very little variability in the first test for proximal effects. That is, the wire can pierce the core at radius 0 or at radius ID with little difference. Shortening the wire loop into a tight turn lead to less reactance and more resistance. However the difference between the two tests is barely out of the statistical noise.

> KG4IVT At H O T M A I L dot C O M

You can make the 2m from a cb antenna no problem, but you may have
trouble with that type of antenna at the house. It requires a good
ground plane to function properly. You might be better off making a 1/2
wave antenna instead. It requires no radials to function as the 5/8
does. But I have made a 2m 5/8 from a cb antenna. I slid the fluted
covering off and replaced the many windings with a coil for 2m. It ended
up only needing maybe 4-5 turns. Wasn't too big a deal, but does take a
little prying to get the cover loose on the type that will let you slide
it off. if you are trying to reduce TVI, a 5/8 ant with a poor radial
system is the last thing you want. The decoupling of the coax to the
antenna is poor. You want a well decoupled antenna that is well away
from the other feedlines. The TVI you have now is likely fundimental
overload which is fed to the tv on the shield of the coax leading to it.

Thanks, Richard, for running the experiment. Your results mirror my experience.

I imagine that you'd start seeing the effect Cecil refers to if you used a very low permeability core, like type 2 or 6 powdered iron. In the extreme, as relative permeability approaches one, the core doesn't have any effect, so you'd definitely see an increase. But not with most ferrites.

Dave: I attached a piece of angle between two of the bumper bolts and mounted a ball mount at the left hand corner of the van so the antenna has a 270 degree view of the world. I use a hustler, but I don't see why it wouldn't work for a hamstick if you can put it on a mast. I use no spring on the bottom and guy the mast with 1/8 inch nylon cord merely looped over the antenna and tied inside the rear door. I have a spring between the mast and the resonator, but I'm thinking about removing it. The 80m resonator wobbles pretty bad at high speeds. I use a quick disconnect on the bottom of the mast for easy removal at car washes and parking garages The rear door is completely accessible this way and the antenna can be viewed with the left had rearview mirror. Later vans do not have bolts showing like mine, but I don't know what year they changed. gl, John KC4ZXX

2872. Re: SWR variations: RG-213 and RG-58 feedline

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-10 11:58:56 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3A852D00.5DCE2FB1@eznec.com>
Source record: 170545

The lossier the coax, the lower the SWR. Imagine if the coax has a great deal of loss. You send a signal down it and only a small fraction of the signal you send gets to the end. Only a small fraction of any reflected signal makes it back. So you see almost no reflected signal at the input, even if the output is badly mismatched. For example, if the SWR is, say, 1.7:1 at the load, you'll see 1.5:1 at the input if your cable has 1.1 dB loss, and 1.2:1 if your cable has 4.5 dB loss.

If the cable has just 3 dB loss, you'll never see more than 3:1 SWR at the input, even if the output is completely open or short. With 6 dB, you'll never see more than 1.67:1, and at 10 dB, never more than 1.22:1. A sufficiently long piece of coax makes a fine dummy load.

Another thing that can affect the apparent SWR is a mismatch between the impedance of the cable and the impedance of the SWR meter. The Z0 of cable is often quite a bit different than its nominal value. I've measured RG-58 at over 60 ohms, so a difference as small as you're seeing could easily be due to differences in cable impedance. (When this happens, changing the cable length can also change the indicated, but not the actual, SWR in addition to the normal lowering effect of lengthening I mentioned.)

Unless you have a truly precision piece of measuring equipment, I wouldn't put too much faith in the measurements. And certainly 1.2 is 1.5 are nothing to be concerned about. Reducing it to a perfect 1:1 won't make any performance difference you'll be able to detect.

Hi Steve,
Running the wire under the window sill will have no appreciable affect on antenna performance, as long as the window is not metal framed , such as aluminum.
There will be RF in the Shack on some bands for sure with this set up. and the best way to get rid of it on those bands is to attatch a 1/4 wire to the ground post of the tuner for that band.

Depends a lot on your current age, but it was a very good deal for me.
I bought a lifetime membership in 1977 for around $250. That would
only cover 7 years at the current rate. You know the annual rate has
to continue to increase with time. Just do the math for your own
situation.

Agreed.... I bought back in the 70's and it was a great deal for me. It's sooooo nice just to have QST show up every month.

I was completely inactive for about 10 years and regret having tossed the mags without even looking at them. But I now have lifetime subscriptions to ARRL, QCWA and WorldRadio. One less expense to worry about when I retire.

Hi Dave,

Back in November, I rented a Ford Windstar for a family vacation. I used the HamSticks for 75/80m, 40, 17, 15, and 10m. You made a good choice. I bought Diamond (I forget the model name and number) heavy-duty universal mount with the 3/8ths X 24 TPI female receptical. It's a good, solid mount, and as long as you're certain you have a good RF ground at the place you install it, you'll be in business. I mounted mine on the rearward-most cargo door at the (aft) end (I own pick-ups and dont' know what the back door is called. Hey, it's the back door!) I checked for good continuity of this body panel and found it acceptible. The back door of the Windstar has so much power schtuff, I was not suprised. With a decent VSWR on each band, from my Icom751a at 100w, I routinely worked from Cape Cod, Mass into 8 and 9 land on 75/80 during the day, at least 1/2 the country at night (in between all the arguing children on that band), and similar results on 40m both day and night. Ten and 17 meters were pretty much like hamming from home during the day...if there was propagation and I could hear something, I could work it. I worked Europe in the mid morning, North, South and Central America all day, and into the far East before the bands shut down an hour or so after local sunset. The Diamond mount does not mar or blemish the paint, has set screws on the under side of the mount that once installed, a little dab of silicone will prevent any oxidation. The supplied co-ax is the thin teflon type and did not affect the weather strippings ability to keep out water. Of course, there will be purists out there (and they are not wrong) who will say that the only the optimum place would be dead center of the vehicle and as low to the ground as possible, especially for low band operation, but for casual (albeit permanent) operation, optimumimity is not always practical. Sometimes, just slapping on an antenna and playing with it until you get a good ground and a good VSWR reading, is just as rewarding as a severe case of optimuminality...just make certain (regardless of what you decide to get), that you have a serious RF ground. This will increase your level of optimumlisticness. The HamSticks are a great choice for those of us who just can't justify the expense of a screwdriver-type to our spouces or even to ourselves. The Diamond mount is solid and did not move a bit, nor did the HamStick mounted to it even at highway speed (75-90mph, conditions permitting of course). No, I'm not a stockholder in either company, I just bought the darned things and happen to be very happy with them. The mount was (I think) around $60.00, but I think it to be well worth it. It's bound to last for years and can go from car to car to car, rental, leased, whatever.

Good luck.

Roy Lewallen wrote:
"In the extreme as relative permeability approaches one, the core doesn`t have any effect, so you`d definitely see an increase. But not with most ferrites."

Roy must be right. A core that doesn`t have any effect is the same as air. A one-turn loop in air has more inductance than a straight wire.

Using a low permeability core, Cecil should see more inductance with a 360-degree wrap of the core than he would in passing the wire straight through. As Roy said, high-permeability cores are another story, and should be able to collect the magmnetic flux caused by current in the wire.

Best regards, Richard Harrison, KB5WZI

Mark - sounds like a Cushcraft 215-WB antenna - I've had four of
these over the years, and your description sounds just like it.
Cushcraft is still in business, but may not have parts for this anymore,
as they changed to the 13B2 to replace this antenna some years ago. I
have a manual I could scan for you, but you'll still have to check with
Cushcraft to see if the elements are available.

If all else fails, you could make your own replacement, and it WILL
work - maybe not to perfect spec, but it would work...been there, done
that, too...

You're right, Richard. When I ran the earlier experiment, I must have looped the coax through the core differently than I had intended. As you point out, one can do a 360 degree loop through a core with either the wire passing through the core once or twice. I thought I performed the experiment by passing it through the core once. I apparently passed it through the core twice by mistake. Senility strikes again.

So I am back to my original question. Amidon says that an FT-77-1024 has a "typical 'Z' of 166 ohms for one turn at 25MHz". I measure 28 ohms for one turn at 25MHz. Why the six to one difference between typical and actual?

I once had a toroid core sample kit from somebody (Ferrite, I think) that included in the mix, some plastic "toroids." I can guarantee that there was a difference in inductance between a straight wire passing through the hole and a wire wrapped around the form.

As Roy says, it all depends on the permeability as to whether or not the shape of the "turn", or the spacing between multiple turns has an effect on the inductance.

Just think, if a straight wire through a plastic donut had the same inductance as one wrapped around the donut, we wouldn't need baluns. The infinite number of little donuts delivered with the coax (the jacket) would be all we needed <g>.

I got one of those diamond van hatch mounts (model 400-3/8) and
mechanically it's fine. I position it right above the tail light lense
with 4 set screws. I can remove it easily. It's high enough that the
loading coil on the 40M hamstick is above the roof level and not too
high to be a problem with trees etc..
I have a balun in line. I did have trouble with the thin coax on the
mount flexing too much and breaking the shield. Might want to secure
it to the mount with a ty wrap to stop the flexing.
Get good signal report considering..and I can remove it when the XYL
wants her van back.

I used the hamstick with a 3-mag mount dead center of the van roof, but I found that there was no place/way to easily ground it (the mag mount doesn't give you a ground through the paint!) and matching the hamstick was difficult. And worse yet, the wind noise at freeway speed was induced through the mag mount to the roof and into the cabin, driving you nuts with a "wishy-whistle" sound, for lack of a better description.

I now have a license-plate mount, which I reinforced with extra bolts, and can mount the hamstick to it. It has a solid ground to the car via the bolts and the hamstick and the hamsticks resonate great. I am now using an old multiband (40, 30, 17, 10) Spider antenna on the license plate mount with a single fishing line forward to the luggage rack to take some pressure off the mount at freeway speed. It works great.

See my Tech Note in QEX (Sept/Oct or Nov/Dec--can't remember which) for a short article on "Trap-Baluns". These are cheap to build and present a very high common-mode impedance for single-band antennas.

Kevin,

Let me play Devil's advocate here (sorry Reg).

If we ignore the problem of achieving an adequate ground for a moment, the literature (Terman 3rd edition Figure 14-28 for example) is replete with examples of 1/4 wavelength stub and sleeve baluns.

For certain, these are a bit different from tuning the coax itself, but they operate on the same idea, so are they any less likely to be inadvertent radiators?

Isn't it always the case that symmetry is required, i.e. the line should be normal to the plane of the radiator? Coupling after the balun would seem to be

just as likely and detrimental if symmetry isn't maintained, regardless of the type of balun.

Even your "more sensible arrangement" requires a non-resonant line which might be difficult on a multiband system. Isn't a "planned" resonance better than an "unplanned" resonance?

Don't get me wrong; I use a ferrite sleeve balun on my wire dipole, so I'm a believer in that approach. On the other hand, I use a non-resonant combination stub/balun (infinite) balun on my HB Yagi and it most definitely requires symmetry for its operation.

Once again; just playing Devil's advocate.

I responded to the nature of toroids in the statement:
>"...The difference between
>a straight-through wire and one 360 degree loop is considerable."
I speculated the variability observed was not in the difference of
straight wire to tightly wrapped wire, but rather how the turn was
formed on each occasion.

I then presented evidence of how there was no variability that was a
function of tight or loose wrapping of a single turn of 360 degrees.
At some rhetorical level, the loose wrap must qualify as an extended
straight wire.

Lest the readership forget, in a practical world "a straight-through
wire" is not sufficiently described to compare to a 360 degree loop of
wire. ANY measurement of that straight wire has a partial loop buried
in the results. Many measuring devices have leads at least doubling

the length of that measured "straight wire." For the best of all worlds that half hidden loop represents +100% error.... it can only get worse. You cannot determine the characteristics without a circuit, the circuit carries with it irreducible lead inductance and stray capacitance.

This may seem like splitting hairs, but when you get into the scale of error as compared to the scale of measurement; then these hairs are the size of Sequoias. It is the practical implementation of the theoretical straight wire that is forcing this peculiar state of affairs.

Rule # 1 Make it as HIGH as you can.
Rule # 2 Make it as LONG as you can.

(A dipole at 1,000 KHz is 468 Feet long!)

Hi Cecil,

Your report of j0 gives me some concern. I have several
manufacturer's kits (60 - 100 styles and materials) and I typically
calibrate their characteristics against my 4 inch loop at 20 MHz.

For every measure I find reactance.

One bead measures 0 + j8 (# 61 material)
and is representative of the extreme outlier
at the other end I have a tube that presents 135 + j90 (# 43 material)
and to confound there are some with 45 - j20 (# 77 material)

My measurements show these patterns of reactance are repeatable and
correlatable to materials across bulk-constant forms.

Another matter as to your expectation
FT-77-1024 or FB-77-1024?
is with # 77 material, the chart indicates at 25 MHz a Z of ~28 Ohms
presuming FB's form factor this should be multiplied by 3.7

Your measure (aside from my concern) looks like it is for one standard
bead of material # 77.

: Wes Stewart, N7WS

Wes,

The difference is that the resonant part of the sleeve balun is shielded
from external fields. My problem with the set up that Reg mentioned is
that it is specifically designed to have a high Q resonant wire in the
vicinity of the antenna. A low Q resonant wire or a nonresonant wire
will not make much of a problem, however Reg's set up needs the high
Q resonance to give a large impedance to work as a balun. That is, either
you have good choking action because of the high Q resonance and therefore
a likelihood that you will excite this resonance with any small asymmetry,
or you have poor choking action because you have no high Q resonance.

Certainly maintaining symmetry is important to keep from coupling the
outside of the feedline for any system, but you will have to maintain
symmetry to a much higher degree to keep the current on the outside of

a high Q resonant line at the same low level as you would with a more normal feedline arrangement.

The usual current balun gives a large impedance for currents running from the inside to the outside of the shield. One way to make this high impedance is to use a sleeve balun, which essentially places a shorted quarter wave line in series from the inside of the original shield to the outside of the sleeve. The exposed part is the outside of the sleeve balun and the rest of the feedline, and this is not normally a high Q resonant circuit.

As an aside, it's perhaps amusing to notice that if you filled a sleeve balun with ferrite, you would get a high impedance with a much shorter sleeve. You then might notice that the outside of the sleeve isn't doing very much. Removing it gives a W2DU balun. I suspect that for vhf work, including a shield on the outside of the W2DU balun might make its effect more reproducible, but I haven't used one at VHF and haven't thought much about it. You could also put a capacitor across the inner and outer shield and get somewhat higher rejection at some frequencies by resonating the parallel inductance.

Source record: 170469

The difference between S6 and "30 dB" over S9 on my Icom 730 (40 meters, preamp out) is 29.8 dB. So If I assumed that it was 50 dB, I'd be wrong by more than 20 dB, or about the gain of a 50 (yes, 50) element or so Yagi.

Even so, it would hard to make an antenna that's 30 dB down from someone else's in all directions and angles. That would mean an efficiency of 0.1%. A 30 dB difference between your signal and someone else's is probably due to the other station being in the direction of a null from your antenna. Obviously not all stations can be in nulls, but you might also be radiating most of your energy in a useless direction such as straight up. I'm very admittedly biased, but I'd use an antenna modeling program to see what's going on. Again admittedly biased, I suggest downloading the free EZNEC demo from http://eznec.com. With it, you can pretty quickly see what you'd need to get the signal going in the directions you want, and give you quantitative comparisons of different configurations.

But remember that any antenna having gain has it only in some directions
in the expense of others. The more gain, the narrower the range of
angles over which it has gain, and the wider range of angles over which
it's weaker than a lower gain antenna. Going for maximum gain is often a

mistake with an antenna you can't rotate, unless there's only a particular direction or direction(s) you want to communicate with.

The random wire or dipole antenna is the usual response to this question. They do work but is generally not a very good way to go. The problem with these types of antennas is that they take up much more space than most people have and they are basically omnidirectional and non tunable. This often causes problems. The better way to go is a small tunable loop. They are directional so you can null out interference and tunable to reject adjacent frequency stations that may interfere with what you are trying to listen to. Radio Shack sells one that does a good job. The cat.# is 156-1853.

I really should'nt reply since i'm no (EXPERT) but here is some friendly
advice
from a Amateur.
A directional or beam antenna would increase your receive signal strength
by several db's.
Depending on the RF gain or signal multiplication factor of the antenna
would
determine how strong distant stations are received.
Like the other gentlemen said height plays a very important role in
reception,
remember that RF radiation tends to drift skyward from the transmitting
antenna
at an angle less than 20degrees perpendicular to the radiating element.
Try using a signal amplifier or receive preamp.

: I've put up a 75Mhz-800MHz discone and fed it with new RG-213
: terminating with a Type N-connector, however, on both 2 Meters and
: 70cm I'm getting an SWR of 1:1.5. As an experiment, I replaced it
: with RG-58 (of shorter length) terminating with a PL-259 connector,
: and the SWR dropped down to less than 1:1.2.
:
: I'm stumped as to why the lower loss RG-213 is behaving this way at
: 70cm and would be grateful for any advice.
```

The most likely possibility is that either your coax or antenna does not have a 50 ohm impedance at the measured frequency. In that case, the N connector might act as an impedance bump and cause the mismatch.

A type N connector is constant impedance by design over a wide frequency range. This is not true with a PL259 connector. Coax also varies a bit from the nominal rated impedance.

Neither the 1.5:1 or 1.2:1 mismatch is enough to worry about.

There are a number of things that can be tried - not necessary in the
best order. Unfortunately, without some test equipment, it is impossible
to guess which would be best - if any.

1) Install a better antenna.
2) Check connections at the antenna and TV to make sure they are good.
3) Add an amplifier at the antenna (not at the TV).
4) If you are using twin lead - change to 72 ohm coax (will require
an impedance converting balun at the antenna and possibly at the TV.
5) Increase the antenna height.
6) Move the antenna to a different location - sometimes even a move
of a foot or two makes a big difference.
7) Try a different TV - to make sure it isn't defective.
8) Replace the coax/twinlead - to make sure they are not defective.
9) Subscribe to either a cable service or to a satellite service.

Rick:

"Ground", it's nice when you have it where you want it... but, heh, heh... it's never where you want it.

And, speaking of "conventional baluns", if you could find a good place to "ground" a Faraday screen placed between the primary and secondary of a voltage balun you could get pretty good common mode rejection out of the thing.

The problem is that, according to Murphy's Law, "ground" is always inconveniently some distance [usually not a negligible fraction of a wavelength] away from where it's needed!

<<<<<<<<<<<<<<
I know that a ground plane is needed for a 1/4 wavelength monopole antenna.
I'm trying to gain a good understanding of why this ground plane is needed.
>>>>>>>>>>>>>>>

I'm certainly no guru, but maybe looking at it this way may help.

Take your typical 1/2 wave dipole in free space. Now, turn it 90 degrees so that it is vertical. You now have an omni-directional antenna with an impedence of 75 ohms, and you need to run the feed line straight out to the side. Now, if you split the bottom of the antenna up the middle and fan them out, you now have a 1/4 wave vertical, and the feed line can come up from the bottom. With the radials at 90 degrees, the impedence is about 30 ohms. At about 45 degrees the impedence is 50 ohme, and no matching network is needed.

If I remember correctly, radials need to be 5% longer than 1/4 wave.

I can't recommend one to buy, but I can suggest one to avoid. Earlier this year I bought a Diamond RHA627 50/144/430 MHz antenna. It has a BNC connector but comes with an SMA adapter. I can't find a frequency on any of the three bands or anywhere else where it's not very noticeably worse than the stock VX-5R antenna, despite being considerably longer. It was a total waste of money.

Source record: 170495

Even an ideal voltage balun will create common mode current if it's presented with a load that isn't perfectly balanced with respect to ground (the "cold" side of the input). Fundamentally, the perfect voltage balun forces equal voltages on each side of the output to ground. If the load impedances on each side aren't identical, this results in unequal currents in the two sides. It's easy to show with simple nodal analysis that the difference current ends up as common mode current.

The classical 1:1 voltage balun has three windings. Two of them are connected like a current balun. The third, or tertiary, winding effects the voltage balance. If the loads on the two sides of the output are identical, the tertiary winding carries no current, so it doesn't do anything in that case. So from the standpoint of common mode current, the tertiary winding does nothing at best, and at worst it produces common mode current.

These are not the result of any imperfections, but occur even if the transformer is perfect.

For more discussion about this, see "Baluns: What They Do and How They Do It", in the _ARRL Antenna Compendium_, Vol. 2.

Richard,

Apparently I'm not being clear since I agree with you, but that is not the situation I was addressing.

If you are careful to not excite the resonant line or in the microwave case, the "metal insulators" with common mode currents you can of course use them. However to use Reg's set up as a balun, you need to make the outside of the feedline resonant just like those metal insulators and therefore you must be much more careful than otherwise about induced current. For example in the microwave case, correct me if I'm wrong, these supports run perpendicular to the conductors. That way they aren't excited. They aren't run partially parallel to the conductors or they would have the problem I am talking about.

I may have missed it, but I thought Reg was replacing a general current balun with his setup. If you specialize, for example, to a half wave horizontal dipole 1/4 wavelength up over perfect ground with the feedline dropped vertically to the ground, then I agree that Reg's method works. Hams often feed antennas that are not well balanced, and often the feedline is dressed so that it can pick up energy from the antenna. In this case you want to suppress both the current from the inside of the shield to the outside, and the induced currents from the antenna fields on the feedline. Reg's set up solves one problem, but exacerbates the second if it exists. A normal current balun solves the first and does not change the second.

shared these priceless pearls of wisdom:

->Effect of paint pigment on Antenna performance...
->
->Does anyone have data or experience regarding the effect of
->paint pigments on antenna performance?

We've been involved with the design and installation of antennas inside the wings of "plastic" (i.e. fiberglass-resin) airplanes for many years. We have had reports, now over 20 years old, that there is a German brand of paint that had measurable effects on aircraft painted with that paint, but I haven't had any information on this particular unnamed and rumored brand for twenty years.

Other than that, paint on a plastic airplane seems to affect the operation of these antennas (75-350 MHz.) not in the least.

Kevin, W9CF wrote:
"They aren`t run partially parallel to the conductors or they would have the problem I am talking about." (1/4-wave metal supports)

Agreed. The question is the size of the problem. If the feedline is perpendicular to its dipole for a 1/4-wavelength before becoming not equidistant from both sides of the dipole, it`s not going to pick up a lot of r-f.

If odd multiples of a 1/4-wavelength are used for a coax transmission line well grounded at the radio, that line is going to reject most energy directly fed from inside the coax to its outside surface.

A lot of coax radiation doesn`t hurt anything anyway. A low dipole doesn`t have much of a directional pattern. Many users would just as soon have an "L-antenna" or an "inverted-V", so a little pattern corruption from feedline radiation may be inconsequential or beneficial. As long as r-f isn`t annoying anybody in the shack there may be no problem.

Depends on the antenna and paint. If the antenna is metal and is painted where there is no loading coils or traps and the paint does not bridge over the feed point then it will have no noticable effect. At a very high frequency it might have the effect of lowering the resonating frequency a very slight ammount, but still probably not noticable in every day use.

If the antenna is enclosed in a fiberglass encloser and it is painted with a paint that has metal particals in it, then there will be some effect on the antenna.

Don's DK3 is good but High Sierra HS-1500 is better.
http://www.hsantennas.com/info/
It comes with ALL the parts. You do not need to run around looking for
something to make a coil cover from. It also has a great finish and mounting
brackets are available.

Has anyone ever tried using "multiple elements" on an MA-5 similar to how Hustler does with a VP-1 Tri-Band adapter on their coils? I can't see why it shouldn't work (as long as you use some good guy lines to stabilize it) I'd appreciate any feedback , thanks

Richard-
The simplest answer is to refer you to any of several books on amateur radio. (amateurs are almost the only class of users that need general purpose tuners). The ARRL handbook and Antenna books would be high on the list. The Houston library probably has copies. Since MFJ makes MANY tuners,and has their manuals on-line, try going to www.mfjenterprises.com, to see general info on typical units.

The classic tuner circuit is a "T", with the top bar consisting of two variable capacitors in series from the transmitter to the antenna, with an inductor from the center connection between the capacitors and ground (the post of the "T"). for most HF tuners, the capacitors are about 250 max, but for 6M, they would be less.

The successful use of a tuner will depend on having a way to measure the outgoing and return signals. Most modern tuners incorporate a bridge and two meters for this. However, there may be a way built into your tranceiver to do this.

I hope this is a start on getting an answer.

> don't know how significantly this may affect its performance.<

A while ago, I spray painted PVC pipe with Ultra-Flat Black Krylon and tested in my microwave oven to see if it would become lossy and heat due to the addition of the pigment. I discovered the treated PVC sample didn't heat anymore than an identical sample of untreated PVC.

If painted PVC isn't affected by high power at 2 GHz, your HF antenna likely won't be affected by non-metallic spray paint.

Mike,
The MA-5 does work well, but it also has a few characteristics
of all fibreglass antennas. Namely, they all tend to eventually
'break' because of the beating they take from tree branches.
I would suggest using any other 'bumper mount' except kenwood's.
Their mount just isn't worth what it costs. Kenwood has one of the
'best' springs I think I've ever seen, HUGE! Probably not worth
it's cost, but will hold a '48 Desoto without too much 'sway' to it.
(You still need a 'guy', though)
The MA-5 isn't the 'best' mobile antenna on 80-40 meters, sort of
a narrow bandwidth, but if you don't move around too much, not a
problem. Like anything from Kenwood, you 'pay' a lot for the 'name.
Guess it depends on what's available.

Helene,
Painting shouldn't make much difference if the paint is
non-conductive. Don't paint the feedpoint junction, or the
trap junctions (if any).

Hi Tom,

You need to read the fine print. The value you are reading off the chart(?) or out of a table(?) is the value normalized to one standard size of bead. The form factor for the FB-77-1024 is 3 to 4 times that value (and is labeled something like Z factor). The properties are dependant upon bulk, and Cecil's core is bigger (3 to 4 times so) than the average bead that is used as a reference by Amidon.

This is why I speculated that Cecil measured a bead, and got his notes mixed as that reading being for the core discussed here. (Otherwise, Cecil, your analyzer is one sick puppy - my guess is that you have miss-identified the material).

Message-ID: <cnAh6.250$k7.50367@ruti.visi.com>
Source record: 170427

I am new to this - so help me out even if this is a dumb question please. I just got a Yaesu FT-847 radio. I currently have a 2 meter antenna. The back of the radio has 4 antenna connectors. I am interested in connecting my 2 meter antenna to one of the 4 connectors on the back of the radio. I would like to protect the radio from me accidently transmitting to the wrong antenna port. Is it possible for me to get a triplexer and a single dummy load and connect the remaining three open antenna out jacks to the single dummy load via the triplexor? To add another small twist - one of the open antenna out ports is a type "N" not a type "M". is there a simple adapter i can get if the triplexer only has type "M" connectors? Please set me striaght if this is way off base. Thanks!

Helene Maxwell wrote:
"I`m putting up a vertical HF antenna among some trees and would like to spray paint it so it isn`t particularly visible, but don`t know how significantly this may affect performance."

Among trees may affect performance depending on proximity, size and density of the trees.

Tower painting is better done with brush, roller, old sock, etc., than by spraying unless this is done in a special facility.

Painted antennas usually perform the same as unpainted antennas when both are new. If the paint protects the conductive surface of a radiator, it may perform better than would a corroded radiator.

Look around. Nearly all AM broadcast towers are required by the FAA to be painted distinctively according to their regulations to reduce air navigation hazards. Performance difference due to painting isn`t worth mention.

For microwaves, no performance penalty from painting is usually significant. You almost never see an unpainted microwave dish., and there is no specification for non-conductive paint. The smooth dish reflecting surface underneath the paint must be conductive anyway. and paint isn`t thick enough to change the dish geometry or performance. The dish won`t be thrown into a microwave oven, and if it were, its behavior would be the same with or without paint, if any practical purpose were served by inserting the radio dish in an oven.

Best regards, Richard Harrison, KB5WZI

Kevin,

I may be a bit dense but I've never let that stop me<g>. If I understand Reg's proposed situation (I note that he has been conspicuously absent since pleading for comments) he has a line only 1/4 wavelength long from the feed point to ground.

I believe we all agree that the purpose for using the balun in the first place is to prevent part of the differential current inside the coax from becoming common-mode current on the outside of the line. Therefore, however it is implemented, it should (does) present a high impedance to the common-mode current while not messing around with the differential current.

For the sake of discussion if we accept that the differential-mode current is independent of the goings on on the outside of the cable we should be able to do away with it and replace it with an ideal generator at the feedpoint of the antenna.

So now there is for example, a quarter wavelenth high, half-wave long horizontal wire, center-fed with an ideal generator and a vertical quarter wavelength coaxial structure symmetrically placed under the feed point and grounded on the bottom end.

The center conductor of this structure is the original coax braid and the outer conductor is the balun sleeve.

If I understand what your are saying (always a dubious proposition) this structure is less likely to radiate if excited than if the sleeve was removed.

I may be wrong but I believe the answer is that there will be no difference.

You may argue with justification that this is a very contrived situation. So let's remove the ground and make the cable a random length. The result is unpredictable but does it ever matter whether the sleeve is there or not? I don't believe that it does.

If the line structure is asymmetrically placed, there will be coupling to the line regardless of the method used to prevent that portion of the common-mode current that results from the transmission line current. Sleeve, bead, or whatever, it makes no difference.

What the world needs is coax with a ferrite-loaded jacket.

Tom,

Just my opinion, but regarding your inability to justify the expense of a screwdriver, I couldn't help noticing that you obviously have $160 invested in your mount plus the antennas ($60 + $20 X 5 hamsticks). For an additional $50 you could've found a screwdriver that, in its most basic form, would outperform those hamsticks by a significant margin. That's just an observation, not a criticism. Of course, you also have the "spouse" factor to deal with as most of us do, or have had.

In my case, I found the extra $50 to be well worth the money in terms of the added performance and the convenience of not having to change antennas every time I want to change bands. If you can persuade the spouse and get hold of the plans ($5), you can build a screwdriver for quite a bit less. With scrounged tubing and PVC forms, it can be done for as little as $40.00 if you have access to a lathe. I make mine out of black Nylon because it is less brittle, resistant to UV rays, and handles about as much power as you want to throw at it.

Well, the shipment from Amidon was labeled FB-77-1024. I suspect someone screwed up on the brochure. In the text, they say the typical 'Z' is given for one "turn" but the illustration shows one "loop" with the wire going through the core two times. For what it's worth, the alleged FB-77-1024 measures 32+j11 ohms for one wire on my MFJ-259B. A T-200A-2 iron powder core measures 13+j16 ohms for one wire. All at 25MHz.

Bill Turner, W7TI wrote:
"The one that KFI has down in Orange County, CA. (is the best AM radio antenna)".

My records show KFI as a non-directional 50-KW station on 640 KHz.

KFI`s antenna is excellent for its frequency and purpose. It would receive Ames, Akron, Norman, St. John`s, and Cuba, perhaps, on 640 KHz. It would also do well on the rest of the broadcast frequencies. It doesn`t have to be resonant. But, hooked to a broadcast receiver in place of the KFI transmitter, most of the time it would likely hear a noise jumble on 640 KHz.

A better antenna for a listener is probably a tuned rotatable loop that can be adjusted for the favored direction and frequency.

Best regards, Richard Harrison, KB5WZI

I am not familiar with that particular radio, but if there is a
triplexer made that covers the bands that come out of the back , then
you can use one dummy load and the triplexer.

The type M connectors don't seem correct either. Are you referring to
the connectors as being a so-239 ?

LOL! So are mine! I make mine with Nylon (no PVC at all) and #14 wire for higher Q. Up to 3" dia. 700 watts on the 2" and full legal limit on the 3 incher. Coil covers are supplied as well as switches and matching. Now, I use a separate coil that has a feature to allow for adaptability to different kinds of Quick Mounts. If one is not going to use a Quick Connect, the coil is simply screwed onto the mount and the antenna mounts to the top of the coil. If one is going to use the excellent Quick Connects sold by Henry Allen (and me because I know the inventor! LOL!), then the brass inserts are removed from the ends and the coil is simply slid over the bottom stud. Why no "toroids"? They seem to give trouble on the upper bands whereas the simple coil easily provides a good feedpoint impedance everywhere. And if your situation changes, it is very easy to just change the tap.

Jerry
K4KWH

Somebody suggested I should use Delrin, but upon consulting my plastics supplier, I discovered that Delrin is brittle and subject to breakage whereas the Nylon is VERY tough and, while stout, has a little "give" in it. It also handles UV very well---especially the black Nylon.

Do it on the coax itself. My speedometer used to run all over the place
and I wound 6 turns of the coax on a small form right at the antenna.
This stopped that as well as my rear window defogger light glowing while
transmitting. I suppose the antenna was coupling with the rear fogger
wires until I did this.

Well, thanks to all that replied about my CB antenna question but I have yet another one. I currently am running a discone in my attic for 2m and because of the way the cable and satellite lines were run, I interfere with them both and can't really do anything about it until I am able to re-run those cables when it warms up. However, I want to try and build a dipole in my attic in hopes of correcting this TVI problem. First off, will this do it? Or am I just going to be stuck in the same boat with the interference problems? Second, I have read about how wire diameter affects the resonance of the dipole. What are some recommended diameters or lengths for those different diameters on 2 meters? Any help is appreciated. THanks!

Place a bead every 12 inches or so. Alternate between type 43 and type 77 to get maximum frequency coverage and to de-resonate along the entire length of the braid. I have done something very similar to this, using 12 feet of RG58 between xmtr and tuner and 5 inch bead spacing. It reduces braid RF conduction from tuner to xmtr by 12 to 18 dB, 3.5 to 29 MHz (measured).

Well,

That's fine and I am happy you have had success with Fords. Not all of them are "bad". My Dad drove Fords from 1940 until 1984. When the dealer convinced him to drive a 1980 Buick Limited, it seemed to have taken the letters "LTD" out of his vocabulary! He STILL drives Buicks. I don't "hate" Fords, I just couldn't get them to work for me. But I do fondly remember some of Daddy's Fords--like our '65 Galaxie 500 that was completely faithful and was smoothe as silk. I was 17 years old when the car was new and I can still "smell" that scent of it--that new car smell.

Now as to the "fast" thing, I might argue with you there! LOL! I had some mighty quick 327/350 Chevys in my day. LMAO!

Best,

Jerry

Wes Stewart (nospam_n7ws@arrl.net) wrote:
: Kevin,

: I may be a bit dense but I've never let that stop me<g>. If I understand Reg's
: proposed situation (I note that he has been conspicuously absent since pleading
: for comments) he has a line only 1/4 wavelength long from the feed point to
: ground.

: I believe we all agree that the purpose for using the balun in the first place
: is to prevent part of the differential current inside the coax from becoming
: common-mode current on the outside of the line. Therefore, however it is
: implemented, it should (does) present a high impedance to the common-mode
: current while not messing around with the differential current.

: For the sake of discussion if we accept that the differential-mode current is
: independent of the goings on on the outside of the cable we should be able to do
: away with it and replace it with an ideal generator at the feedpoint of the
: antenna.

: So now there is for example, a quarter wavelenth high, half-wave long
: horizontal wire, center-fed with an ideal generator and a vertical quarter
: wavelength coaxial structure symmetrically placed under the feed point and
: grounded on the bottom end.

: The center conductor of this structure is the original coax braid and the outer
: conductor is the balun sleeve.

: If I understand what your are saying (always a dubious proposition) this
: structure is less likely to radiate if excited than if the sleeve was removed.

: I may be wrong but I believe the answer is that there will be no difference.

: You may argue with justification that this is a very contrived situation. So
: let's remove the ground and make the cable a random length. The result is
: unpredictable but does it ever matter whether the sleeve is there or not? I
: don't believe that it does.

: If the line structure is asymmetrically placed, there will be coupling to the
: line regardless of the method used to prevent that portion of the common-mode
: current that results from the transmission line current. Sleeve, bead, or
: whatever, it makes no difference.

: What the world needs is coax with a ferrite-loaded jacket.

: Wes Stewart N7WS

I agree that the behavior of the outside of the line is independent of
whether the sleeve is there or not. The choking action will typically

be better in the usual sleeve balun if the sleeve is there since the impedance of the shorted 1/4 wave line making up the balun part will typically be higher. The picture I had from Reg's description was an off center fed random wire with the feedline arbitrarily placed; apparently this isn't the picture anyone else had. As others have said here, for a half wave length dipole with a reasonably perpendicular feedline, the impedance of the 1/4 wave length wire, making up the dipole, hooked to the shield side often is low enough compared impedance of the outside of the feedline that no balun is needed at all for reasonable performance.

Let me try to design a Reg style balun for a VHF yagi. I have a driven element matched to 50 ohms and requiring balanced feed. I connect the coax to the feedpoint, and I need to produce a ground 1/4 wave length away. The simplest way I can think of is to put a set of 1/4 wave radials extending out from the feedline one 1/4 wave length below. I think we all will agree that a generally better design bends these 1/4 wave radials back up along side the coax shield, and connects them together, to produce a sleeve balun. That is cheaper, mechanically simpler, does not radiate, and does not expose the resonant part to external fields. As it stands we have built a 1/4 wave ground plane antenna on the bottom of our yagi. Now the ground plane is vertically polarized, and as far as direct connection is concerned, it is end driven and therefore will not couple much to our yagi, so this will probably work OK as far as keeping the feedline current low. However if the antenna were not so symmetric, you have designed a resonant section which will increase the pickup from any vertically polarized field. I agree that in this case the outside of the coax would in any case be excited, but if it is not explicitly built to be resonant at the driving frequency you have a lot more chance of the induced current being small.

I think this thread has failed to differentiate between painting a metal antenna and painting a radome (including a PVC pipe with the radiators inside).

I have seen many airborne, shipboard and ground radomes, or antenna covers, with "DO NOT PAINT" warnings prominently displayed. I presume there are sound reasons for this and have previously seen the microwave oven test recommended as a simple test for radome materials.

This is far from my area of expertise, but just to add another question since this group seems to harbour a good collection of genuine exeperts, I have noted that large radomes (with do not paint notices) are sometimes made of many sections assembled with large numbers of metal bolts. I assume the bolts do not significantly affect the performance?

Dave.

The last Amidon merchandise I purchased (a few years ago) contained cores of a different material than marked on the package. I have no idea how widespread this problem is, but I can say for sure it happened once. As I recall, it was something like type 43 instead of 77. Sure enough, your reading indicates type 43 or something similar. Type 43 has a Q of one (R = X) between 10 and 20 MHz; above this it becomes more resistive. But type 77 hits this point at more like 1 MHz, so at 25 MHz, you won't see much reactance compared to its resistance. I suggest poking one of the cores with an ohmmeter as another check. If you read infinite, it's not 77.

With these ferrite cores, a single turn reading gives a good idea of the Q of the material itself, and you'll see roughly the same Q for any reasonable number of turns. I don't think this is the case for the low-permeability powdered iron cores, though. You can get much better Q with type 2 material than your measurement indicates. I think your reading might show so much loss just because the low permeability core isn't doing much with a single turn. For the powdered iron core, it would probably be better to use several turns -- say, 5 -- then divide the impedance by the square root of the number of turns to infer an impedance per turn squared. There's also the possibility that the measurements aren't very good. Try measuring a piece of wire and a direct short. The only analyzer I've used, an early Autek, had quite a bit of residual series inductance. If your analyzer does, you'd be better off measuring several turns with the ferrite material also, just to make the fixed error smaller with respect to the measured value.

I got this antenna from a friend who got it from someone else, you know the drill, for free you can't complain. Anyways when I got the antenna it was in pieces and from what I see in the MFJ catalog and on the web, I believe that I have it assembled in the right order. Problem is that regardless of how I adjust all the set screws, I can not get better then 2.1 on 2 meters and 2.3 on 70cm on any part of the band.

Here is how I have it assembled:
1. First section is the thickest radiator adjusted to 11.25" in length.
2. Next comes a trap 3 5/8" long x 1/2 wide at it's widest point
3. Next is the next smallest radiator at a tuned length of 11.25"
4. I cant tell if the next piece is a trap or what. It's gray with a small black stripe in the center.2.25" long x 3/8" wide. I don't see it in any of the pictures I look at.
5. The next radiator is the same diameter as the last at 5.75" in length.
6. Then another trap at 4.5" long x 1/2" wide.
7. Finally is the last radiator with a static tip, 16.5" long.

Please keep in mind that the measured lengths are not the cut lengths, just were the radials go into the traps.

If someone else has this antenna could you provide me with the following:

*The order in which the antenna is assembled. This includes if you can measurements of each of the parts.
*What kind of SWR readings to you get on each band.

My ultimate plan is to get this working as a temporary base antenna with some radials for a new apartment location until I get time, permission, and resources to setup a base antenna.

BTW, when I tested the SWR, it was on a trunk mount on my car where I currently run a diamond antenna with a low, 1.3 or less swr.

Thanks
Chris

2975. Re: painting an antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-11 22:27:00 UTC
From: Ralph Mowery <rmowery@dialpoint.net>
Message-ID: <3A8711B4.EBA0C3B4@dialpoint.net>
Source record: 170448

Radomes if painted have to be painted with paint that will not affect the microwaves. It is just easier for them to print 'do not paint' on them than it is to give more details about what kind of paint to use.

The big microwave dish type antennas are using the dish to reflect the waves to and from the focus point just as a big searchlight does. The bolts do effect the anternna gain by covering up some of the radiation path. It is just that it is not enough covered up to make much differance. Calculate the ammount of square feet in the reflector and the total area of the bolts and you will see the percentage is not that great.

Hello all,

I am looking for a replacement 440 Mhz HAM repeater antenna for a non-hostile (high wind/snow) environment.

I have used the Diamond 500 in the past (I used the 2 meter side of the antenna for a remote base)

I would like to go to a single band antenna and have been debating on the Diamond F-718A or the Hustler G6.

Does anyone have any words of wisdom on these, or other antennas?

I don't want to spend the $$ on a station master.

Thanks in advance.

Ralph

You might be stuck with the cable interferance if the antenna is very close to the TV coax lines. YOu should not be causing problems with the cable if they are using a good grade of cable and their connections are ok. Two meters will cause some problems with chanels 17 to 19 on cable as they are using those chanels that correspond to the 2 meter band. If you can get 20 or 30 feet of seperation between the antenna you should not cause problems on other frequencies. If you are sure it is comming in on the cable, they have to clean up their equipment.

The diameter of the wire , number 20 or even if you use 3/4 inch copper tubing will have very little practical effect on most dipoles. While it will have some effect , it will tend to make the antenna shorter than the caculated length as the element diameter gets larger.

When making beams it is important to make the diameters the same as calculated. This seems to be the direct opposit from what I said above. That is because for most simple home built antennas you just cut them long and trim them after they are installed for the lowest SWR. To make beams work efficiently there are many complex calculations to be done and it is hard to vary them for the best gain in a cut and try method.

Folks:

A good question to ask, since the recipes for the various magnetic "materials" are often secrets, nd proprietary to their owners/manufacturers, is what exactly is the makeup of the various materials and what are the manufacturing controls used to ensure consistency.

e.g.

Ho, exactly does one manufacture type 77 material or any other such esoterically coded material?

What are the constituents, what is the grind/fineness of each, what is the binder used,and it's properties, how is the baking time controlled, etc...?

Who knows???

Then, when the material is cast into it's final "ceramic-like" form, how is it's manufacture "traceable" by we consumers?

I am sure that suppliers like Amidon begin with the best of intentions when it comes to quality control, but what exactly is their record, do they have SPC "Statistical Process Control" data to support their specifications, etc...??

What?

Since a 2 meter dipole is only about 38 or 39 inches long, why not
just build one out of ordinary 14-ga. wire or lamp cord, connect it to
your coax, and, yes, you could put it in the attic, but you could also
just tape it to your window, wall or whatever -- try to get it away
from your TV coax. If you're only trying to hit local repeaters, that
may be all you need.

The thickness of the wire should have little practical effect on the
length of the dipole legs.

A high-level modulated r-f power amplifier is a mixer for r-f and audio. Some r-f received by the transmitting antennas gets mixed in with the locally produced r-f. The received energy is so much less than the desired energy being transmitted that it is hardly noticed.

During adjustment of our 790 KHz directional array, we often could hear KABC in Los Angeles, almost 2000 miles from Houston.

More importantly, we could also hear KTRH, 50-KW, just 20 miles and 50-KHz away at 740-KHz. It not only appeared in our bridge receiver. We could hear KTRH when we were unmodulated and turned-up the volume on our monitoring amplifier. It appeared in the noise and distortion on our measuring equipment but it was always more than 50 db below our fully modulated level, and that was the maximum allowable.

Those extraneous carriers and noises get modulated at very low levels and transmitted as carrier noise. The station`s transmitting antennas are also receiving.

Best regards, Richard Harrison, KB5WZI

The dimensions are correct for FB-77-1024 not for FB-43-1020. The only
other #77 material I have are FT-82-77 toroids which are much smaller
than the FB-77-1024. The side to side resistance on the alleged FT-82-77
is 300k while the side to side resistance on the smaller cross section
FT-82-77 is 30k. Should the bigger core have the smaller resistance?
Two of the FT-82-77 toroids with one turn through them read 23+j0.
Guess I need to contact Amidon about this.

Ralph Mowery wrote:
"Radomes if painted have to be painted with paint that will not affect microwaves."

Yes. A radome should be transparent to microwaves. It is usually just a protector in the microwave path.

An explosion in the microwave population has required a lot more "high performance" disjhes. These have shields to screen parabolas and parabolic section reflectors from undesired signals.

Some dish antennas are fitted with cylindrical extension shields so that they look more like arc-lamps.

Other high performance antennas have so much shielding that they look like giant scoops.

The dishes resembling arc-lamps often have a membrane stretched over the open end of the barrel. Like the radome, you don`t use conducting paint on the cover membrane.

Frizz wrote:
"I want to try to build a dipole in my attic in hopes of correcting this TVI problem."

First line of defense is separation between the interfering and interfered devices.

You lose 22 db in the first wavelength of travel from a radiator and 6 more db every time you double the distance thereafter,

For a quick and dirty dipole try the "coaxial".
For 2m, strip 19 inches of jacket from one end of a piece of your favorite type of flexible coax, and discard it. Skin back the exposed shield over the remaining jacket, exposing about 19 inches of insulated inner-conductor.

The exposed insulated inner-conductor and the skinned-back shield now comprise a 1/2-wave dipole. Put an appropriate coax connector on the other end of the cable and you are ready to try it out.

Find a place for the antenna that works and causes the least interference.

Best regards, Richard Harrison, KB5WZI

I am unfamiliar with the circuit details of this particular set, however I would hazard a guess that it has a built in AE selectivity circuit.

All of the old Valve/Tube sets had Tuned AE sections and the selectivity of the set was appropriate to the band being listened to.

This approach was dropped somewhere along the line when Semiconductor receivers became available in volume.

A big mistake dropping that front end selectivity, witnessed by all the argument about IMD etc.

The manufacture that wants to be seen as head of the market will need to reintroduce the tuned front end.
If the Kenwood R-5000 for instance had an integrated tuned front end it would be a world beater. Having to manually tune the preselector when changing bands is a bind.
The ideal set would have a front end preselector that tracked the tuning.

Probably the only thing that has stopped them doing it is the cost and the increase in box size.
Certainly an additional RF amp is the very last thing that is required.
a typical mixer has a noise temperature of 2,500°K equivalent to 10 dB noise figure. in order to reduce the noise temperature of any set a bit of gain ahead of the mixer is needed. 20 dB (x 100) reduces the noise temperature to 25°K
This is ridiculously low on the HF bands that have a sky temperature range of

Frequency ~|~ T sky
2,000,000,000 Hz ~|~ 4 °K
1,000,000,000 Hz ~|~ 25 °K
500,000,000 Hz ~|~ 159 °K
250,000,000 Hz ~|~ 1,005 °K
125,000,000 Hz ~|~ 6,340 °K
62,500,000 Hz ~|~ 40,000 °K
31,250,000 Hz ~|~ 252,383 °K

15,625,000 Hz ~|~ 1,592,429 °K
7,812,500 Hz ~|~ 10,047,546 °K
3,906,250 Hz ~|~ 63,395,728 °K
1,953,125 Hz ~|~ 400,000,000 °K
976,563 Hz ~|~ 2,523,829,378 °K

A range on the HF Ham Bands from 250°K to 400 Million Degrees Kelvin
So an RF amplifier will only overload the set on bands up to 18 MHz.

Below this Frequency a straight Mixer type front end can be used without any degradation. That is probably why direct conversion sets are so good on 20 m The Kit by GW4BWE RC14 Direct Conversion Receiver is a prime example that you don't need excessive technology to listen on 20m.

I have converted an RC14 into a panoramic display, (ideal for contesting), and it is every bit as sensitive as the R-1000, R-5000.

Below 18 MHz a direct AE to Mixer with gradually decreasing IF gain until it is less by 40 to 50 dB less at 160 m . You only require sufficient gain to amplify the noise to sufficient amplitude to make the detector operate correctly with it's maximum dynamic range. The ideal level for diodes to operate at is -22 dBm for the noise power into it. This fits nicely onto the characteristic curve of the majority of commercially available diodes.

More gain just takes up useful dynamic range.

Remember you can NOT improve upon the Signal to Noise Ratio at the output terminal of the AE (Antenna).

It is pointless to add more gain than is required; in fact it is self defeating.

The biggest advantage to a receiver it to remove from the input signal, noise and adjacent channel signals, that can cause problems when amplified to mix with other signals within the IF of the set producing all sorts of birdies and ghost signals.

Match the gain of your set to the purpose to which it is to be applied.

Example,
SSB voice on 160 m in 2.4 kHz band width.

Input Noise is KTB
Doing it in DeciBel form; like real Engineers do it. ;)

-198.6 dBm/ °K/Hz (Boltzmann's Constant in Log Form)
86 dB °K = 10 log(400,000,000°K)
34 dB Hz = 10 log(2.4 kHz receiver bandwidth)
adding gives
-79 dBm of noise at the front end.

We want -22 dBm into the detector for the noise floor of the receiver.
Required IF gain is

(-79) - (-22) = 57 dB of Gain required between AE and Detector.

Most commercial Communications receivers will have at least 90 dB of IF gain because doing the same sum for 10 m the input noise power is 32 dB less than on top band.
So to receive 28 MHz properly we need 57 + 32 = at least 89 dB of IF gain.

The designer will make the gain a bit more to give him a margin for the AGC circuit etc and the fact that the Mixer has about 10 dB insertion loss and other considerations.

They seem to wind up with IF gains available of between 100 dB and 110 dB (and even more?)

Add 20 dB RF gain in front of the Mixer to improve the noise temperature (Noise Figure) and the set is grossly overloaded on top band (160 m).

An available gain of 130 dB when only 57dB is required to do the job.

We need to loose some 60 dB of Gain.
The manufactures fit an attenuator that will loose up to 30 dB of that gain at the front end.

What is ideal is to set that attenuator equal to the gain of the RF Amplifier and use the RF gain control to cut back the IF gain by the remaining over gain value.

One way to find that set point for the RF gain is:
Put RF Gain at minimum.

Increase the AF gain until you can just hear the noise from the set.

Now increase the RF gain until that noise just doubles.

Reduce the AF gain to a comfortable listening level where the noise is JUST perceptible.

At this setting you can get no more performance out of the set by changing the settings.

At this point you desperately need the preselector filter between the set and the AE in order to reduce the out of Band noise contribution.

At this point you can increase the RF gain a little to restore the noise to a comfortable listening point.

If there is any rare DX out there and your AE is capable of delivering enough signal the the set will certainly hear it when set up this way.

If you have performed this procedure on a quite Sky Noise day or time of day you will need to either decrease the RF gain if the noise level is higher or you can increase the RF gain a little if you are listening on a quieter day / time than when you set-up the set.

Leave the AE attenuator setting alone to be equal to the gain of the RF amplifier.
Mathematical refutations only please. :)

In my long career in electronics one of my tasks was to aberration correct the radomes of missiles; as the phase shift through what was primarily an aerodynamic shape bent the RADAR beam by having differential phase shift.

In order to perform this task a detailed profile of the microwave delay through the dielectric material was made.
From the punched paper tape so produced the radom was then mounted on a spray rig and dielectric varnish was applied one layer at a time to the thin dielectric areas.
Up to 15 coats were applied at a session to produce an electrically uniform phase front through the Radom.

If any element of a proposed antenna system is phase sensitive then any sort of paint will cause some phase change.
Obviously the amount of phase change will be proportional to the thickness of the paint film, the dielectric constant of the paint when dry and the wavelength of operation.

At 9mm a coat of paint say ten tho thick = 0.03 wavelength.

At the frequencies used by most Hams the fraction of a wavelength represented by a coat of paint (less than 0.001") will be considerably less. Those working in the millimetric region will be only to well aware of the problems that materials can cause.

Any material will have three properties the permativity, permeability, resistivity.

Water is a good example:
It has a dielectric constant of 80 or greater and a loss tangent of 0.3

It's presence in food stuffs makes the Microwave oven a practicable device. The loss tangent is responsible for converting the microwaves into heat and transforming the water into steam which is trapped within the food, this cooks the food.

Many paints will have a high permativity, but a low loss tangent, probably much lower than water.

I would expect therefore more degradation due to rain than due to most paints unless they had been deliberately loaded with materials such as

Carbon Dags.
A colloid, [fine powder], of carbon in a suspension fluid [sticky stuff].

When the dried resistivity of the paint is 377 Ohms per square then you have an Ideal Radio Absorbent Material [RAM]. This is the stuff that is painted upon stealth aircraft, applied to towers and structures that produce unwanted Radar echoes.

Generally speaking many paints will not have any effect, but I wouldn't take it for granted, especially if you happen to pick up some very old paints loaded with lead etc.

I think that I used the pronunciation "sodder" during the reign of queen
Thatcher; quite a lot actually, religiously at least once a day.

Now it would be nice to pronounce it "SOLD HER"

Any of you Yanks want her?
going cheap $0.02 ; will make special price reduction for a quick sale.

Of course the correct pronunciation of the name of this useful workshop
material is as the later, but drop the 'H'.
It is slovenly to drop the 'L'; besides, I want her to suffer. REM
'L' = HELL

I hope that this bit of nonsense will prompt you to use this word carefully
and with respect; and don't catch your clothes on the soddering iron.

Amidon is a retailer; they don't manufacture cores (as far as I know). They used to, and I believe still do, sell ferrites manufactured by Fair-Rite Corporation, and powdered irons by MicroMetals. Both these manufacturers provide extensive infomation about their products on request, and have it posted on their web sites. The last time I looked at Amidon's offerings, it looked like they also have a few Magnetics parts. This is also a reputable manufacturer that provides good and detailed information.

Ferrite manufacturing is indeed proprietary, so I doubt you'll get detailed information about the manufacturing process. (I've seen a presentation of the general process, although with certain key details omitted, and it's quite interesting. It struck me as being as much an art as a science.) However, if your application requires statistical data or other special information, I'm sure either vendor would be glad to accommodate you for an appropriate charge.

Fair-Rite sells cores of the same dimensions made from several different materials. So the dimensions won't tell you what material the core is made from. Amidon could have ordered the wrong thing, gotten the wrong cores from their vendor, or mixed up cores from their stock.

I'd expect a larger core to have smaller bulk resistance, but wouldn't be surprised if it doesn't vary quite a bit from lot to lot. I don't believe bulk resistance is well controlled. About the only thing I'd say for sure is that neither of the cores is type 43 or a lower permeability material, and if they're Fair-Rite cores, both are 70 series. For a given size core, I'd expect all the 70 series ferrites to show roughly similar impedances at 25 MHz.

23 + j0 is more like what I'd expect from type 77 at 25 MHz, instead of the nearly equal R and X you reported earlier.

Sometimes. But I'm also talking about situations in which there are two or three parallel frequencies, in different bands, with two out of three words intelligible on the best one, but which one is best changes from minute to minute. How are you going to cope with that with a preselector in the way? I'm talking about trying to ID a station below the threshold of intelligibility, where if they put on music I can check to see if it's the same tune on a parallel frequency (you can follow a tune at lower S/N than that required to understand voice). How can you switch back and forth fast enough with a preselector in the way?

Ham radio is not SWL, and ham radio technique is often not optimum for SWL. The original question was about "SW" antennas, so I assume it was about SWL.

> Why don't you just buy a mobile phone instead, that way you can also
> have selective calling.

Please, no insults. You are apparently not interested in SWL, and therefore don't understand much about its techniques, but some of us find it far more interesting than ham radio.

> volume would probably also be unacceptable.

But the most expensive receivers have the fanciest front end attenuators and the least front end selectivity (the $4000 WJ HF-1000 has a "wide open" front end). Engineering for high dynamic range requires expensive expertise and sophisticated test equipment. Front end selectivity is a cheaper substitute, just cookbook engineering (and it doesn't work if the interfering signal is close in frequency to the signal of interest).

> Note that on 18 MHz and 24 Mhz the excess noise at the front end is
> nearly
> 20 dB over what it would be if you had an Rx specially designed to just
> cover those Ham bands.

Why would an SWL want a receiver especially designed for the ham bands? There's so much more to listen to outside them! :-)

Your analysis assumes (1) that noise that makes it through the front end filters contaminates the signal, and (2) that the quantity of noise is linearly related to the bandwidth. If the system is linear, it is the IF filter bandwidth that counts, not the front end, so (1) is false. If the system is nonlinear (overloaded), (2) is false. (2) is also false if what you call "noise" is, in fact, a few strong narrow band signals (this is the usual cause of overload).

A few days ago, we were debugging the downlink from MIT's HETE satellite ("137.96 MHz: All HETE All the Time") to our Kenya ground station. OK, actually a colleague at Malindi was doing the debugging: we at MIT were just kibitzing over the net. Anyway, our friend at Malindi did the following thing: he set up a simple dipole antenna on a workbench, attached a GaAsFET preamplifier, and fed it to his microwave spectrum analyzer (I think he just wanted assurance that we had turned the transmitter on the satellite on!).

HETE radiates about 250 mW (24 dBm) of low data rate telemetry with a 300 Hz bandwidth. At a range of 1000 km, the "space loss" is 135 dB.

Polarization loss averages another 3 dB. Under free space conditions, we would thus expect to receive -114 dBm. Natural noise density at this frequency is about -141 dBm in a 1 kHz bandwidth according to the CCIR curves: for a bandwidth of 300 Hz, the noise is thus -146 dBm. C/N is thus expected to be 32 dB. While this free space/natural noise analysis is a bit optimistic for a makeshift setup indoors on a bench, nevertheless a strong signal was observed on the spectrum analyzer.

There was no front end filtering in this system: bandwidth was several GHz. According to your method I should therefore increase the noise in the above calculation by ~70 dB. If this had been the case in reality, our satellite would have been completely undetectable, 38 dB below the noise in this setup.

> Having struggled to get the gain you then throw it away. :(

As a designer of high performance signal chains (I designed video chains with 3 electrons RMS noise for NASA's "Chandra" orbiting observatory), I can assure you that getting gain isn't a struggle. Indeed, once you've put in all the amplifiers you need to do the mixing, gating, summing, isolation, limiting, and impedance transformation required in a typical signal chain, the challenge is often getting rid of all the excess gain in ways that don't cause you other problems.

If all you needed was enough gain, you could make a communications receiver with four transistors.

If you have a receiver noise floor 25 dB below the noise density at the frequency of interest (a very common situation on HF), it makes perfect sense to switch in 20 dB of attenuator: it may drastically reduce intermodulation, and the loss of signal has a negligible effect on system sensitivity.

> In this context using a filter is like using a selective weed killer,
> using an attenuator is analogous to using a flame thrower.

Your analogy is misleading. Overload is more like being blinded by glare. An attenuator is like putting on sunglasses, blocking the excess light. A filter is like a sun visor. A preselector? Well, that's like taking a large box, cutting a small hole in it, painting the inside black, and putting it over your head. Peering out throught the hole, you'll see very little glare, and when the hole is aimed just right you may be able to see what you want. I think most people would find this a crude and debilitating way to reduce glare (although it would work). Similarly, a preselector is a crude and debilitating way to reduce overload.

>

Depends on how you define "better". The KFI antenna is a low-angle one due to the presence of an effective ground plane (I presume; haven't personally inspected it). The loop, without a ground plane, is a high-angle antenna and would probably come in second for serious DXing. A rotatable loop does have the advantage of being able to null out interference.

Bill, W7TI wrote:
"Depends on how you define "better". The KFI antenna is a low-angle one due to an effective ground plane---."

True. No inspection needed. The FCC requires an efficient antenna system. It is a vertical radiator with a good ground system. Broadcasters maximize radiation in a horizontal plane to the extent allowed by economics and regulations.

For "better" reception, signal strength is not as important as signal to interference ratio. At least, Ames, Akron, Norman, St. John`s, and a station in Cuba share the air in and around North America with KFI on 640 KHz. Adjacent channels tend to spill-over into the desired channel in most receivers.

If you are near one of the stations on 640 KHz or one of its adjacent channels, it is likely you will only be able to hear the near station most of the time. At a distance from them, you may be able to pick one from the pack by positioning your loop antenna. The loop will also discriminate against man-made and natural interference in its null directions. KFI`s antenna doesn`t have any null directions.

Best regards, Richard Harrison, KB5WZI

Depends why you have the tvi with the discone. If it's due to overload
from being too close, likely you will have the same problem with the
dipole. I guess you could give it a try, but I wouldn't hold my breath
waiting for the tv to clear. Do you have any other farther away places
to mount the discone in the attic to get away from the other lines? Why
will rerunning the coax help? If they installed something that is not
right, I'd complain to the cable co. and have them fix it. MK

LOL!

That's OK. Those were the days, eh? That's when we were young. Some-
how going extremely fast just doesn't appeal to me anymore. Now I'm
not averse to cruising at 80 if I can, but I'd get very nervous if I
were to go as fast as I once did. I once drove my Dad's '58 Fairlane
at 120+ and his '65 Galaxie across the Albemarle Sound bridge (2 miles
across) at 100+ (all the little 289 could muster). Not too long ago,
I crossed that same bridge and marveled at how narrow it is. I asked
myself, did I REALLY go 100 mph on THAT bridge?! I shuddered to think of
it! How could I have been so stupid? But, hey, I was 17 and indes-
tructable, right? Mmm, mmm, the things I got away with back then! And
if Daddy had known.....

Hey, I betcha you remember just driving around aimlessly for the sake of
driving--every chance you had, in the car cruising. Buying gas for
18.9 cents per gallon, taking 10 bucks with you and your date to the
movies and a burger at the local drive-in and coming home with change!

One thing on the Ford/Chevy argument while I'm reminiscing. I bought a
new '67 Caprice coupe that year. $3600 list, $74.70 per month. I
bought the 327 heads, manifold/Quadrajet, and put the duals on. And
yes, I had an HF radio in it--I was the only 19 year old with a BIG
Master Mobile antenna. My best girl-chasin' buddy had a '64 Fairlane he
named "Snoopy" and even went so far as to paint the little dog on the
front fenders. He still is a good artist. He swapped out the little
260 CID V8 for a 289 4BBL, did some cam work, exhaust, and a Hurst shif-
ter. Even tho we were buddies, he was going to leave my Caprice in the
dust. One night, leaving the skating rink, the "big" race began. I
was first turning out onto the highway, and Joe whipped out into the
left lane and gunned his Ford. Next, all you could hear was motors
gunning and the distinctive moan of a Quadrajet. Now, my big Chevy was
MUCH heavier than Joe's Fairlane, but imagine his surprise when he
was unable to pass me! He was just able to get his nose beside my door.
We slowed down and tried another rolling start. Same thing. Anyway,
looking back, I don't see how we raced for 8 miles without attracting
the attention of the local constabulary.

Nowadays, I'm more content with powerful ham radios.

Garry, I've never read such a load of so-called technical jargon which
should really be classified as rubbish.

Why don't you just state outright you can paint your antenna any colour you
like, with any sort of paint you like, and nobody will ever notice the
slightes difference.

I once outran three Maricopa Co. deputies on my Kawasaki Z1B. Now
I wonder what would have happened if the chain had broken at 135mph.
That bike redlined at 60mph in first gear with four more gears to go.

True, but there are exceptions and Gary brought up the radome that may act as a lens which could make a radar cock-eyed. His job was correcting the radar`s vision. Plastic lenses are sometimes used to focus microwaves. For Gary`s purpose, all that was needed from the radome was neutrality.

Another exception to "do as you like" in the USA is the painting and obstruction lighting of tall towers which must meet FAA requirements. Short towers are not regulated, except near airports.

Best regards, Richard Harrison, KB5WZI

That's what I have been told and talked to a friend using one last night.
He was at least 10 miles or so from the 6m repeater and was full quieting.
He lives practically across the street from me and my stock antenna is poor.
I have the other Madol (now Comet) antenna that is soft rubber about 3" long
for 2/440 with SMA and it sure works well for its size and is very
convenient. As Roy Lewellen said, the Diamond he bought was a poor
performer. So was the only Diamond I ever bought. In terms of the VX5R's
receiving performance, I think it has a lot to do with its small size as my
largest hand held radio, which is my old trusty IC-32AT, can hear stuff my
others cannot. Even Alinco DJ-X10 communications receiver does not hear as
well as the Icom, even with the same antenna. Next smaller is FT-50 and it
hears better than VX-5R. I borrowed a little VX1R and it was deaf compared
to the others. VX-5R sure is neat little radio tho!

Reg, if you think what Gary wrote is rubbish, you obviously know nothing
of what's been done with microwaves and RADAR in the the past quarter
century or so.

Radomes have been trimmed for their phase response for a LONG time now; all
of Gary's post is accurate.

A "thin" layer of fiberglass and paint may totally transparent at 1.8 Mhz,
but 18 Ghz is something entirely different.

> Why don't you just state outright you can paint your antenna any colour you
> like, with any sort of paint you like, and nobody will ever notice the
> slightes difference.

At frequencies below microwave, probably true. Since lead paint hasn't been
around (in the US anyway) for decades, most any modern paint is probably OK
at HF.

3017. RE: Discone Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-12 20:48:26 UTC
From: alainmv@aol.com
Message-ID: <20010212154826.12352.00000561@ng-fs1.aol.com>
Source record: 170393

I've got a RS discone 10' above the roof; it's been there for almost 2 yrs and has served me well. LAFD/PD are still received well from 160+ miles away. Recently, due to a few wind storms, two radials from the "cone" have been broken off, but scanner performance has not dinimished that I can tell.

What function do the cone radials provide? At what point will signal strength suffer? Does missing adjoining radials (one next to the other) make the antenna more directional?

Lastly, what should I be looking for as a replacement antenna? I monitor mostly 30-50 meg and 150.

Many, many thanks!

Alain @ Palomar Mtn.

3018. FS: Portable "wind-up" multi-band Dipole's.

After marketing our wind-up reel antenna for SWL's, several hams have approached us about manufacturing a DIPOLE model. So we've done just that and call it the "YoYo-Tenna Deluxe". We've taken two of our YoYo-Tenna wind-up antennas and combined them into a PL-259 coax fitting. You can add coax...or...just plug it straight into your rig or tuner! 40 ft. per reel, so operation is from 10 thru 40 meters. (One ham suggested "stacking" them...or running them in series to cover 75/80 and 160. I'll leave that up to you guys...) If you want to see what a single reel looks like, please visit our website. - http://qth.com/dwm - Remember, no shipping and handling will be charged on the Deluxe model since you are ordering two...and we give free shipping on two or more YoYo-Tennas. (Total cost - $29.90)

Thanks for your time and 73!

Bill - WA8MEA @ Jackson Co., Michigan QRP Club Station - KC8BCR

At your local hardware store, you can obtain plastic 'dry wall corner protector' cost $ 3.00 / 8 ft pieces, cut into 4 " strips use #24 copper, 3 " center holes and make your own, use hot glue gun to permanently hold wire. use scissors to cut , cut lengthwise and into 4 " lenghts, makes enough for 25 ft ladder line. 600 ohm.
Also plastic coat hangers are as good and cheaper, cut into 4 " lengths.

3021. Want to build a 6m ant.

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-12 22:07:24 UTC
From: JRW <johnrwells@hotmail.com>
Message-ID: <99Zh6.72$Cw2.3027@news1-hme0>
Source record: 170395

Hi

I want to build an antenna made with wire for 6m, centre freq: 51MHz (UK 6m band).

I want to make it so I don't have to keep tuning it, i.e. cut it to the optimum length and I want about 50ohms. I could put up a 1/4 wave vertical piece of wire with some radials or a dipole or inverted V. I would also like to try a Yagi with one reflector, a driven element and one director. How do i calculate the spacings and lengths of each element and how to I calculate the folded radiating element? Oh, and how about a loaded dipole, are they any good and what are the dimensions?

Thanks,

John

3024. ARRL Yagi Analyzer vs NEC2

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-12 22:23:46 UTC
From: Tom Merendino <tmerendi@fore.com>
Message-ID: <3A886272.230B8E6D@fore.com>
Source record: 170397

Hi,

I have run the exact same 7-element Yagi design (858MHz) thru both ARRL's Yagi Analyzer (YA) program (dated 1994) and thru NEC2D (dated 1996). The program environment is Windows NT 4.0. I modeled both runs in free space, with no boom compensation nor taper schedule in either model. Just a plain, simple wire yagi with identical dimensions in each program.

I noted that NEC2D reported feedpoint impedance values about one-half of the feedpoint value reported by ARRL's YA.

I wasn't expecting exact calculation of impedance between the two programs, but I was sort of expecting them to be within, say plus/minus 20% or so - not to be off by 100%.

Does anyone have experience with the impedance accuracy as modeled by these two programs as compared with the actual impedance of the antenna once it is built?

Thanks in advance.

Shielded loop. No contest. Also, any AM broadcast antenna will need
to be vertically polarized -- a horizontal dipole will be very poor. I
was looking at the BE Radio website, as they used to have a very nice
design for one, but I can't seem to find it right off. www.beradio.com
was where it was....

From: kg4ggx@aol.com
Message-ID: <20010212174348.12373.00000574@ng-fs1.aol.com>
Source record: 170401

Hi all
I'm looking for recommendations on a coaxial choke balun for a 6 meter dipole.I plan to make the choke from RG-8X. At this time, I've made one from RG-8X that is 4 feet of coax, 5 turns at about 2.5 inches diameter. How far off am I? Do I need a longer length of coax, more turns, smaller or larger diameter? I'd really like to use an effective choke to keep the feed line from radiating since 6 m seems prone to RFI.
Thanks for all replys.

>in most receivers.

I see why we're not in perfect agreement here. I think in terms of DXing very weak, far away signals where signal to noise ratio is most important. You're thinking of listening to relatively strong stations where interference is the main concern. For my preference, a 5/8 wave vertical with good ground plane is near-ideal for BC reception. For yours, the loop is best.

Like I said, it depends on how you define "better". :-)

Source record: 170403

Just a point of clarification. Rho in these equations is the magnitude of the reflection coefficient, not the reflection coefficient itself. The reflection coefficient is actually a complex number. Rho is unfortunately used to sometimes represent the (complex) reflection coefficient and sometimes (like here) its magnitude, although some people (me included) prefer to use uppercase gamma for the complex reflection coefficient and lowercase rho for its magnitude.

I know Wes is at least, and probably better, acquainted with this than I am, and the equations are of course just fine. I'm commenting just because I've often seen confusion among the reflection coefficient, its magnitude, and its real part.

> polarized the QRM received is much greater than with a directional beam
> antenna.

I don't believe most noise is inherently polarized more one way or the other when it's radiated. But noise which is vertically polarized can propagate a few miles via ground wave, while horizontally polarized noise can't. So you might hear more noise with a vertically polarized antenna than a horizontally polarized one. This would be man-made or perhaps static noise coming from within a few mile radius. Noise and QRM from far away is as likely to be horizontally polarized as vertically, so the polarization of the antenna wouldn't make any difference for these.

> 2. You transmit a vertically polarized signal, so only vertical antennas
> can receive you well. Likewise, you receive vertically polarized
> signals better than horizontally polarized signals. i.e., verticals
> can only talk to verticals.

This is true only for line-of-sight communications. If you're communicating via the ionosphere, troposphere, meteor scatter, and so forth, the polarization is changed in an essentially random manner when the signal reflects or refracts. So there's no inherent advantage to one polarization over the other unless you're doing line-of-sight communication. The laws of physics don't know what we consider to be signals and what we consider to be noise, so noise and QRM from distant sources also arrive randomly polarized.

Vertically and horizontally polarized signals do behave quite differently when reflected from the ground. This causes the pattern of a vertically polarized antenna to be a lot different than the perfect-gound ideal case unless reflection is taking place from salt water. You can find more information about this in the ARRL Antenna Book.

I am new and looking for a mobile HF antenna to easily mount on a Pontiac Transport van (1997). I read with interest an earlier post about Hamsticks, but want multiband. I saw someone referenced a spider antenna. Are these true multiband, or do you have to swap the coils? My local ham club has suggested a screwdriver, and the expense is not a problem, but the mounting would be a concern. Any suggestions?

EZNEC and NEC-Win use the same basic calculating engine (NEC-2), so should give very similar answers. (A possible exception is when modeling Yagis made from telescoping tubing. EZNEC "corrects" for NEC-2's error by substituting equivalent constant-diameter elements -- see "Stepped Diameter Correction" in the EZNEC manual index. I assume that NEC-Win uses a similar algorithm, but don't know if the implementation is the same.) NEC4WIN95, I believe, uses MININEC as its calculating engine. This can result in dramatically different results in some situations like quads or antennas with low horizontal wires, but results should be very similar in most cases.

Bill Turner wrote:
""For my preference, a 5/8 wave vertical with a good ground plane is near ideal for BC reception."

Reciprocity rules, and many a-m broadcasters would say your choice was best for them, too.
They would be just about right so long as they needed 360-degrees of uniform coverage.

An agency I worked for during the cold war operated a European broadcast monitoring station in Germany. It busily recorded many different outlets. It studied and used the information so obtained. The listening post was in a very quiet spot and did the best it could to get clean reception. Multiple tower arrays were phased to enhance reception and place nulls in the directions of intefering stations. These could be quickly readjusted to receive a more fruitful outlet at a different hour.

The multi-tower array wasn`t the best antenna to receive all outlets. Loops with huge ferrite cores and some loops with air-cores were also used. Whatever proved best was used.

I doubt that a non-directional antenna was ever the antenna of choice. Even with a strong signal and little interference a directional would have been chosen just for the insurance.

All the h-f reception was done not only with directional antennas, but with triple diversity as well.

I agree that KFI has a fine non-directional antenna, but for best reception of distant signals your chances are better with a directional antenna.

When I lived in Europe, after midnight when most of the Europeans had signed-off, I used to listen to Edward R. Murrow and the CBS News from WCBS in New York. If WCBS happened to fade, I just rocked the dial a tad to WWL which was carrying the same program in New Orleans. I was using a Beverage antenna with a Hammarlund SP-600. It always gave good results.

The Beverage is a good example of what works. It is inefficient and gives no where near the strongest signals. But, it surely gives a good signal to noise ratio because it is quite directional.

Ther problem with KFI`s antenna as a receiving antenna is that it is very efficient but completely non-directional, except for the null at its zenith.

You usually have plenty of receiver gain, especially if you are fortunate enough to have a "Super Pro". In the broadcast band, the signals are usually competing with atmospheric noise, other external noise, and unwanted signals, not internal receiver noise. So, I still contend that the main worry is signal to noise, not feeble signals.

Best regards, Richard Harrison, KB5WZI

Well, the little Select-A-Tenna broadcast-band AM loop really makes
signals pop out of the noise. The faintest signal will literally jump
out at you with the loop, even when used with a cheap radio.

The main problem is finding dx signals that are relatively in the
clear, and not covered up by local stations.

I know that Jack Belrose, VE2CV, wrote one or more articles in QST on
the topic of OCFDs several (5?) years ago. Maybe someone can point you
to the particular issue(s). I recall that he had a lot of difficulty
preventing feedline radiation, even with a balun. Feedline radiation is
sometimes not a problem, but it sure can complicate matters if you're
trying to duplicate somebody else's system, because the feedline itself
is part of the antenna so has to be duplicated also.

>coefficient and sometimes (like here) its magnitude, although some
>people (me included) prefer to use uppercase gamma for the complex
>reflection coefficient and lowercase rho for its magnitude.

Roy raises a good point. Tom Bruhns already took me to task for a
somewhat careless use of rho. Although I did define it below, as Roy
and Tom said, it is often used as a complex number.

I too prefer upper case Gamma for the complex number and rho for the
magnitude but unfortunately the literature is full of confusing usage.
Some of the literature was even published by Tom's employer, the
former H-P, now Agilent (how do you pronounce that again?)

My autographed copy of Steve Adam's, book "Microwave Theory and
Applications", published by H-P, shows on page 23:

" |Gamma| = rho "

Similarly, my handy dandy H-P "Reflectometer calculator" sliderule
says that SWR = (1 + rho) / (1- rho) which bears a striking
resemblence to what I wrote below.

But then in H-P's App Note 77-3, "Measurement of Complex Impedance
1-1000 MHZ", it says that rho is a vector quantity and it shows:

SWR = (1 +|rho|) / (1 - |rho|)

Finally, the best reference I have is General Radio's "Handbook of
Microwave Measurements" (out of print but reissued by Gilbert
Engineering) and it says that Gamma is complex and rho isn't.

So I guess the thing to do is do as I did below and define the damned
thing every time you use it<g>.

Sigh. And I didn't even realize the inconsistency of useage. I had only seen (or at least only realized I had seen) rho used equivalently with Gamma. I apologize for being so uppity about rho...but for sure agree that it's by far best to always define it, with either words or a formula. Thanks for bringing this up, guys. (Now I'm going to slink off and review some of my own references...)

Cheers,
Tom -- K7ITM

dapastaguy,
A 'spider' is usually the base part of the antenna with
an adapter that allows you to have 4 resonators instead od
only one. Do they work? Yes, how well depends on how much
trouble you take to tune all of them.

Rob,
I'd have used a coil diameter of around 6", and 8 turns.
It isn't very critical. Small diameter coils with RG-8x is
asking for problems from conductor migration (center wire
gradually moves to the outer side of the coil, changes
impedances, and can eventually short out).

While we're already discussing this subject, I have a quick question about antennas and paint. I have several different VHF & UHF mobile antennas that have a black finish on them. Because of the weather they've been exposed to over the last couple of years here in Michigan, some of the black finish is chipping off. Is there a generic type of spray paint I could get at the hardware store that would be okay to use on the antennas without hurting their TX/RX performance? I know it should be non-metallic, but what specifically should I be looking for in the ingredients?

Thanks,

Noah

That might not be too far off. In the arrl ant book they state appx 8
ft-8 turns for 20m. 4 ft-6-8 turns for 10m. "For rg-58, which is nearly
the same size as rg-8x". So I would think appx 3 ft-4to 6 turns might be
fairly close to optimum just by guessing. You are not too far off from
that, and it may be working ok. If you have no problems using it, I
would consider it good enough. MK

No problems doing that.
I could put up a 1/4 wave vertical
> piece of wire with some radials or a dipole or inverted V.

Those would work too.
I would also
> like to try a Yagi with one reflector, a driven element and one director.
> How do i calculate the spacings and lengths of each element and how to I
> calculate the folded radiating element?

You can get a table of lengths for NBS yagis in the arrl ant book. Also
you might be able to find on the net. You could even use a modeling
program to calculate one, and also optimize for your specific uses. But
I wouldn't bother with the folded driven element. I prefer a normal
driven element grounded to the boom, and fed with a gamma match, or
whatever. I think the easiest and most rugged way to build.
Oh, and how about a loaded dipole,
> are they any good and what are the dimensions?

I wouldn't bother with that on 6m. You have room for full size. Or
should anyway. I just put up a 6m antenna the other day. It's a base fed
1/2 wave vertical I threw up to be able to try the band. Mainly for fm,
rptr use. I also plan something for SSB/CW. Maybe a yagi. 6m fairly dead
around here on the whole, but was surprised today on 52.525. I keyed up
and ID'ed not expecting any answer, and had a guy actually call back.
Wonders never cease...I've been trying to stir up a little more local
interest in 6m. I'd never worked 6m up until recently when I got a radio
that has the band. Might as well try it and get my moneys worth. MK

I think I would prefer the loop most of the time for AM-BC listening just judging from past use on different radios. I like the abilty to to null stuff out. I got a bonus when I bought a new ic-706 recently. It's a great AM-BC receiver for its size. And real good audio too. It uses a fairly wide 8 kc AM filter which I think really helps the audio. Many ham rigs have too narrow of filters for am use and don't have very good audio. But I've been using the 706 for this lately with my 160-80-40 combo dipoles, and has been doing real well. It's quickly becoming my favorite AM radio. It's also real good to SWL the HF bands. Alas, the longwave is usuable , but nothing to write home about. The lower the freq, the worse it gets. MK

Less dangerous anyway, unless you stick a finger in an amp..:(..They
just don't make cars like they used to.

My first car was a 65 chevy impala sport sedan that my dad bought new. I got it in about 1973 or so when I first started driving. It was one fast puppy. Had one of the first 396's. The difference in the sport sedan and regular was the lack of a pillar between the front and back side windows. I remember it was quite a head turner at the gas stations when it was new. The 396 rat motor got the gas jocky's attention every time in 1965-66. The 396 excelled at high speed racing. It didn't get warmed up until you hit 100. Then it started sounding and acting like a race car. :) Most had the small block 327's until then. I had quite a few other big blocks in later years, but now drive only 6 bangers. A V6 in my car, and a I6 in my truck. We used to terrorize the freeways in my younger years. I thought nothing of blasting down 610 at 110 mph. But of course in those days, there wasn't near the traffic "or cops" there are now. We used to race all the way across town driving home from work late at night. "My 396 against a mopar 383 a friend had usually. But my fast driving days are long gone. And the weird part is I never got a speeding ticket until I became a slow driving semi old fart. Then I finally got one. I guess justice will prevail... MK

3054. Re: painting an antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2001-02-13 13:16:34 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <96bc46$h1f$1@uranium.btinternet.com>
Source record: 170329

The subject matter is painting amateur multiband vertical antennas, operating frequency 1.8 to 30 MHz. This newsgroup is not conducting a seminar on a 30 GHz sideways-looking, terrain-mapping radar for the surface of Mars.

Keeping to the subject, at 29MHz, a coat of paint, 0.002" thick, on a 1" diameter antenna conductor, height = 8.5 feet, will reduce its resonant frequency by less than 0.00018 percent. This is equivalent to a shift in frequency of 52Hz at 29 MHz.

Is this slight difference noticeable ?

Reg

Source record: 170330

Rob, what you are looking for is the self-resonant frequency of a solenoid wound with a conductor as thick as the outside diameter of the coax you intend to use.

A solenoid, 4 inches long, 2 inches former diameter, close-wound with 16 turns of 1/4 inch outside diameter coaxial cable, has a self-resonant frequency of about 50 MHz.

For other dimensions of coil and coax download in a few seconds program SOLNOID2. In addition to the essentials of coil design this program calculates the self-resonant frequency due to parasitic capacitance, and the impedance at the resonant and lower frequencies.

The PVC jacket on coax will cause some uncertainty in the exact resonant frequency but in choke-balun applications this is a relatively unimportant matter.

(Having said all that, I think a 2" diameter ferrite ring filled with loosely-wound coax does a better job. It has a smaller loss, it has a much wider operating bandwidth, it weighs less and is mechanically more convenient to install.)

Actually, the deputies were engaged in a less than "high speed pursuit".
The thing that sold me on the Z1B was a magazine review article. It said:
"What's it like to ride a Z1B? Ever been shot out of a cannon?" :-)

Nope, not at all.

However, the "subject matter" drifted (as most newgroups are prone to do)
to radoms with Do Not Paint warnings. Gary's quite accurate response to
that drift was proclaimed by you to be "rubbish". I think you owe Gary
an apology.

Paul Radge wrote:
"Yes a rhombic 4 wavelengths per side. I`m trying to find information on how to reduce impedance to feed."

A rhombic may produce about 750 ohms at its feedpoint. Typically this is reduced by using a tapered line at h-f between the drivepoint and a parallel-wire 600-ohm transmission line. The rhombic is typically 1/2-wave above ground which makes the tapered line about that length.

A full wavelength would be a smoother impedance transistion than the 1/2-wave line would produce. Since the wavelength is only 23 centimeters, or about 9 inches, the line could be just a couple of rods.

Ed Laport has a table of parallel-line impedance versus the ratio of line spacing to wire radius, in his "Radio Antenna Engineering". Working this out for AWG 12 wire (.04 in. radius) gives a spacing of 20 inches for 750 ohms, the rhombic drivepoint, and 1/2-in. spacing for 300 ohms line impedance.

A matching section 9 inches or more long (even less will work ok) using AWG 12 or larger wire should be easy to produce as a partial solution to your problem. Larger wire is fine. It wil have a slightly lower line impedance which can be corrected with slightly wider spacing. This is not critical as you will note wide variations in the length of tapered lines used and the wide frequency range that is used with them in a typical rhombic. The rather casual attitude taken with tapered line spacing doesn`t seem to hurt in practice either.

Best regards, Richard Harrison, KB5WZI

Well, Helene's original query seems to have suffered the normal routine of several good answers and several answers to questions which hadn't been asked! Not necessarily a bad thing as we can all learn something from these 'wriggling threads', although they do seem to generate yet more questions...

This business of conductive paint for example, perhaps someone can helpout with an explanation. As I see it I can quite happily paint either my antenna or its 'radome' (i.e. pvc tube etc) with just about any paint I can buy without causing a problem at normal amateur hf/vhf/uhf frequencies. Even painting over traps and connections is unlikely to cause as big a problem as rainwater collecting on these parts. But what happens if I use a conductive paint? I don't think Gary's colloidal carbon paint would cause a problem when applied to antenna elements only, but it may well if used on that pvc radome or over a trap for instance. Am I right in this assumption? Metallic paint was also mentioned in one reply as if it were to be avoided. Is this necessary. Surely metallic paint as sold in aerosol cans for car body repairs consists of fine aluminium particles supended in an acrylic medium and is unlikely to ever form a substantial metal coat. So what effect would this have on the antenna? I reckon none at all - as in normal paint. So has anyone ever investigated this situation with respect to amateur radio use or are we all running on hearsay, guesswork and non-relevant radar techniques? I'm not knocking any of those who responded to the original query but I think there are now several loose ends which ought to be sorted.

Regards,

John, G8OZH

==========
All paints have a high carbon content - just like polyethylene, the finest
insulating material ever invented.

Suppose a thin coating of sump oil + soot + super-glue is to be applied to
an antenna conductor.

Suppose the antenna is 95% efficient, a reasonable value, before the goo is
applied.

Suppose the conductor loss resistance increases by 25%, a ridiculously high
value, after the goo is applied.

On application of the goo efficiency falls to 93.8%

This is equivalent to a loss in signal strength of 0.055 decibels or 1/109th
of an S-unit.

Does this constitute a disaster or is it likely to remain un-noticed ?

Reg.

Cecil,

>Actually, the deputies were engaged in a less than "high speed pursuit".
>The thing that sold me on the Z1B was a magazine review article. It said:
>"What's it like to ride a Z1B? Ever been shot out of a cannon?" :-)
The same could be said for the one time, back in the early 70's I had a
ride in an original big black 429 Boss Mustang.

Few made it to these shores, fewer took that rascal on at the lights.

Well, with the current lifetime membership at $850 for those under 65,
that's 25 years of dues at $34 a year -- but assuming dues will
probably double or triple over the next 25 years (dues were $12 back
in 1978), then you might break even in maybe 10 or 15 years... (the
stock market usually goes down when the Republicans are in the White
House, so don't look for any good investment gains for awhile)

Hi Wes,

Here is an additional reference:

"rho is called the reflection coefficient. It is the
(complex) ratio of the amplitude of the reflected wave to the
amplitude of the incident wave. We shall represent its magnitude
by r. This is:
rho = r * e^j*theta "
HP Application Note #16, Waves On Transmission Lines

I think the confusion of:
>My autographed copy of Steve Adam's, book "Microwave Theory and
>Applications", published by H-P, shows on page 23:
>
>" |Gamma| = rho "
is attributed to the difference between the Reflection Coefficient for
the general line and the reflection coefficient for one point on the

line (or a terminus). Generally the uppercase form is the complex function and the lower case form is the scalar solution.
